EN ISO 13791:2004 (E)

Foreword

This document (EN ISO 13791:2004) has been prepared by Technical Committee CEN/TC 89 “Thermal performance of buildings and building components”, the secretariat of which is held by SIS, in collaboration with Technical Committee ISO/TC 163, “Thermal performance and energy use in the built environment”, Subcommittee SC 2, “Calculation methods”.

This European Standard shall be given the status of a national standard, either by publication of an identical text or by endorsement, at the latest by March 2005, and conflicting national standards shall be withdrawn at the latest by March 2005.

This standard is one of a series of standards on calculation methods for the design and the evaluation of the thermal performance of buildings and building components.

This document includes a Bibliography.

According to the CEN/CENELEC Internal Regulations, the national standards organizations of the following countries are bound to implement this European Standard: Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.
Introduction

This document is intended for use by specialists to develop and/or validate methods for the hourly calculation of the internal temperatures of a single room.

Examples of application of such methods include:

a) assessing the risk of internal overheating;

b) optimizing aspects of building design (building thermal mass, solar protection, ventilation rate, etc.) to provide thermal comfort conditions;

c) assessing whether a building requires mechanical cooling.

Criteria for building performance are not included. They can be considered at national level. This standard can also be used as a reference to develop more simplified methods for the above and similar applications.
1 Scope

This document specifies the assumptions, boundary conditions, equations and validation tests for a calculation procedure, under transient hourly conditions, of the internal temperatures (air and operative) during the warm period, of a single room without any cooling/heating equipment in operation. No specific numerical techniques are imposed by this document. Validation tests are included in Clause 7. An example of a solution technique is given in Annex A.

This document does not contain sufficient information for defining a procedure able to determine the internal conditions of special zones such as attached sun spaces, atria, indirect passive solar components (Trombe walls, solar panels) and zones in which the solar radiation may pass through the room. For such situations different assumptions and more detailed solution models are needed (see Bibliography).

2 Normative references

The following referenced documents are indispensable for the application of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

EN 410, Glass in building – Determination of luminous and solar characteristics of glazing.

3 Terms, definitions, symbols and units

3.1 Terms and definitions

For the purposes of this document, the terms and definitions given in EN ISO 73451995, EN ISO 9251:1995, EN ISO 9288:1996 and EN ISO 9346:1996 and the following apply.

3.1.1 internal environment

closed space delimited from the external environment or adjacent spaces by the building fabric
3.1.2
room element
wall, roof, ceiling, floor, door or window that separates the internal environment from the external environment or an adjacent space

3.1.3
room air
air of the internal environment

3.1.4
internal air temperature
temperature of the room air

3.1.5
internal surface temperature
temperature of the internal surface of a building element

3.1.6
mean radiant temperature
uniform surface temperature of an enclosure with which an occupant would exchange the same amount of radiant heat as with the actual non-uniform enclosure

3.1.7
operative temperature
uniform temperature of an enclosure with which an occupant would exchange the same amount of heat by radiation plus convection as with the actual non-uniform environment
3.2 Symbols and units

For the purposes of this document, the following terms and symbols apply.

4 Determination of internal temperatures

4.1 Assumptions

The evaluation of the internal temperature of a room involves the solution of a system of equations of the transient heat and mass transfers between the external and internal environment through the opaque and transparent elements bounding the room envelope. The procedures given in this document allow the user to determine the time dependent temperature of each component, including the internal air. Accepted assumptions for the calculation of the internal temperatures of a single room under transient conditions in absence of any cooling plant are:

- the air temperature is uniform throughout the room;
- the various surfaces of the room elements are isothermal;
- the thermophysical properties of the materials composing the room elements are time independent;
- the heat conduction through the room elements (excluding to the ground) is assumed to be one-dimensional;
- the heat conduction to the ground through room elements is treated by an equivalent one-dimensional heat flow rate according to EN ISO 13370;
- the effect of thermal bridges are generally neglected, but if they are considered their heat storage contribution is neglected;
- air spaces are treated as air layers bounded by two isothermal and parallel surfaces;
- convective heat transfer coefficients: at the external surface they depend on the wind velocity and direction, at the internal surface they depend on the direction of the heat flow;
- the long-wave radiative heat flow rate at the external surfaces of the room elements is related to a time-independent heat transfer coefficient;
- the external radiant environment (sky excluded) is at the external air temperature (see 4.5.4.1);
- the distribution of solar radiation within the room is time-independent;
- the dimensions of each element are measured inside the room;
- the mean radiant temperature is calculated by weighting the various internal surface temperatures according to the relevant areas;
— the operative temperature is the average between the internal air temperature and the mean surface temperature.

### 4.2 Evaluation of the relevant temperatures

#### 4.2.1 Internal air temperature

The air temperature of a room, at any given time, is obtained by solving Equation (1), where heat flow rates to room air are taken as positive:

\[
\sum_{j=1}^{N}(Aq_{c,j})_j + \Phi_v + \Phi_{i,c} + \Phi_{sa} + \Phi_{va} = c_a \frac{\partial \theta_{a,i}}{\partial t}
\]

where

- \(N\) is the number of internal surfaces delimiting the internal air;
- \(A\) is the area of each building element;
- \(q_{c,j}\) is the density of the heat flow rate by convection (see 4.5.2.2);
- \(\Phi_v\) is the heat flow rate by ventilation (see 4.5.6);
- \(\Phi_{i,c}\) is the convective part of heat flow rate due to internal sources (see 4.5.5);
- \(\Phi_{sa}\) is the solar to air heat flow rate (see 4.5.3.4);
- \(\Phi_{va}\) is the heat flow rate due to the air entering the room through air layers within the elements bounding the room;
- \(c_a\) is the specific heat capacity of air;
- \(m_{a,i}\) is the mass of the internal air;
- \(\theta_{a,i}\) is the temperature of the internal air;
- \(t\) is the time.

**NOTE** Because of the very small value of the term \((c_a m_{a,i})\) the right-hand side of Equation (1) can be assumed to be zero.

#### 4.2.2 Internal surface temperature

The internal surface temperature at element \(j\) is obtained by solving Equation (2), where heat flow rates to the internal surface, except \(q_{c,j}\), are taken as positive:

\[
q_{lr,j} + q_{sr,j} + q_{c,j} + q_{cd,j} + \Phi_{i,s} + \left(\sum_{j=1}^{N} A_j\right) = 0
\]

where

- \(q_{lr}\) is the density of heat flow rate due to long-wave radiation exchanged with other internal surfaces (see 4.5.4.2);
- \(q_{sr}\) is the density of heat flow rate due to the absorbed short-wave radiation (see 4.5.3.2);
- \(q_{c}\) is the density of heat flow rate released to room air by convection (see 4.5.2.2);
$q_{cd}$ is the density of heat flow rate by conduction (see 4.5.1);  

$\Phi_{i,r}$ is the heat flow rate due to the radiative component of internal gains (see 4.5.5);  

$N$ is the number of surfaces delimiting the internal air;  

$A_j$ is the area of room element $j$.  

### 4.2.3 Surface delimiting two solid layers

![Figure 1 - Surface delimiting two layers](image)

The temperature at surface $j$ delimiting two layers in an element (Figure 1) is obtained by solving Equation (3):

$$q_{cd,j-1} + q_{cd,j+1} + q_{sr,j} = 0 \tag{3}$$

where

$q_{cd,j-1}$ is the density of heat flow rate by conduction from the $j-1$ surface (see 4.5.1);  

$q_{cd,j+1}$ is the density of heat flow rate by conduction from the $j+1$ surface (see 4.5.1);  

$q_{sr,j}$ is the density of heat flow rate due to the solar radiation absorbed by the surface $j$.  

### 4.2.4 Surface of an air layer

![Figure 2 - Surface delimiting an air layer](image)

Key  
1 Air layer
The temperature at surface \( j \) of an air layer (Figure 2) is obtained by solving Equation (4):

\[
q_{c,j} + q_{lr,j} + q_{cd,j} + q_{sr,j} = 0
\]  
(4)

where

- \( q_c \) is the density of the total heat flow rate released to the air layer (see 4.5.2);
- \( q_{lr} \) is the density of the heat flow rate received by long-wave radiation across the air layer (see 4.5.4);
- \( q_{cd} \) is the density of the heat flow by conduction (see 4.5.1);
- \( q_{sr} \) is the density of heat flow rate absorbed due to an external source (e.g. solar radiation).

4.2.5 External surface of a room element

\[ j \]

\[ q_{c,j} \]

\[ q_{lr,j} \]

\[ q_{cd,j} \]

\[ q_{sr,j} \]

Figure 3 - External surface of an element

The temperature at surface \( j \) of a room element (Figure 3) is obtained by solving Equation (5):

\[
q_{lr,j} + q_{sr,j} + q_{c,j} + q_{cd,j} = 0
\]  
(5)

where

- \( q_{lr} \) is the density of heat flow rate by long-wave radiation at the surface (see 4.5.4.1);
- \( q_{sr} \) is the density of heat flow rate due to the short-wave radiation absorbed by the surface (see 4.5.3.1);
- \( q_c \) is the density of heat flow rate by convection with the air (see 4.5.2.2);
- \( q_{cd} \) is the density of the conduction heat flow rate (see 4.5.1).

4.2.6 Relevant temperatures for special construction elements

4.2.6.1 Ceiling below an attic

The ceiling, the air space and the roof are considered as a single horizontal element with one-dimensional heat flow. The air space is considered as an air layer, treated in 4.5.2.3 and 4.5.2.4.

4.2.6.2 Floor on ground

The floor and the soil are considered as a single horizontal element with the heat flow treated according to EN ISO 13370. Boundary conditions are specified in 4.4.3.
4.2.6.3 Floor over cellar

The cellar is treated as an adjacent room according to EN ISO 13370. Boundary conditions are specified in 4.4.3.

4.2.6.4 Floor over crawl space

The floor, the crawl space and the soil are considered as a single horizontal element with the heat flow treated according to EN ISO 13370. The crawl space is treated as a ventilated air layer. Boundary conditions are specified in 4.4.5.

4.2.6.5 Glazed element

A glazed element is composed of a number of planes (glazing panes and possibly blinds) which are in thermal equilibrium with one another. The evaluation of temperatures of each plane is made using the following assumptions:

— the heat storage effects in the various planes are neglected;
— the heat flow by convection through the air layers between each pane is calculated according to 4.5.2.3 and 4.5.2.4;
— the density of heat flow rate due to the long-wave radiation between the various planes is calculated according to 4.5.4.3;
— the density of heat flow rate due to the short-wave radiation absorbed by each plane is treated as a source term.

4.3 Room thermal balance

In each equation of 4.2, the time dependent heat flow rates shall be expressed in terms of operators which relate the heat flow rate at the internal surface of each element to the temperature at the internal and external surface, and that of the internal air, by using suitable mathematical models of the heat transfer processes. The temperature of the internal air, together with the temperature of the different surfaces, shall be determined by solving the global equation system at each time step considered. A general expression of the equation system is:

\[
\begin{bmatrix}
\Pi_{1,1} & \Pi_{1,2} & \cdots & \Pi_{1,N} & \Pi_{1,N+1} \\
\Pi_{2,1} & \Pi_{2,2} & \cdots & \Pi_{2,N} & \Pi_{2,N+1} \\
\cdots & \cdots & \cdots & \cdots & \cdots \\
\Pi_{N,1} & \Pi_{N,2} & \cdots & \Pi_{N,N} & \Pi_{N,N+1} \\
\Pi_{N+1,1} & \Pi_{N+1,2} & \cdots & \Pi_{N+1,N} & \Pi_{N+1,N+1}
\end{bmatrix}
\begin{bmatrix}
\theta_{1,1} \\
\theta_{1,2} \\
\vdots \\
\theta_{1,N} \\
\theta_{1,N+1}
\end{bmatrix}
= 
\begin{bmatrix}
\Gamma_1 \\
\Gamma_2 \\
\cdots \\
\Gamma_N \\
\Gamma_{N+1}
\end{bmatrix}
\tag{6}
\]

where

- \( N \) is the number of elements bounding the room corresponding to the internal surfaces delimiting the internal air;
- \( \Pi \) are the coefficients of the unknown temperatures (\( \theta \)) (from 1 to \( N \) relating to the internal surfaces, \( N + 1 \) relating to the internal air);
- \( \Gamma \) are the coefficients of the known terms (from 1 to \( N \) relating to the internal surfaces, \( N + 1 \) relating to the internal air);
- \( \theta \) are the unknown temperatures (from 1 to \( N \) relating to the internal surfaces, \( N + 1 \) relating to the internal air).

The "\( \Pi \)" and "\( \Gamma \)" terms are obtained by rewriting Equation (1) and Equation (2) in order to separate the unknown parameters (air temperature at the given time \( t \) for Equation (1) and the internal surface temperature for each component at the given time \( t \) for Equation (2)) from the known parameters. The form of these equations depends on the solution technique adopted.
4.4 Boundary conditions

4.4.1 Single room

A single room model requires the knowledge of the conditions of adjacent rooms. The two following situations are considered:

— adjacent room with the same conditions (similar rooms);
— adjacent room with defined internal conditions.

If boundary conditions are very different from the above, the simple room model specified in this document shall not be used and it is necessary to calculate the real boundary conditions by a multi-room model able to take account of the heat transfer between the different rooms. This may be achieved by:

a) simultaneous solution of the global system equations for all rooms, or
b) iterative procedure by considering, as boundary conditions for each room, the temperatures determined at the previous time step.

4.4.2 Similar rooms

4.4.2.1 Partition (vertical) wall

Referring to Figure 4, the following boundary conditions are considered:

\[
\begin{align*}
\theta_{a,e} &= \theta_{a,i} \\
q_{sr,e} &= q_{sr,i} \\
q_{lr,e} &= q_{lr,i} \\
h_{c,e} &= h_{c,i}
\end{align*}
\]

(7)

Key

1 Similar
2 Internal

Figure 4 - Partition vertical wall
where

- $\theta_{a,e}$ is the air temperature of the adjacent room;
- $\theta_{a,i}$ is the air temperature of the room;
- $q_{sr,e}$ is the density of heat flow rate due to absorbed short-wave radiation at the external surface of the wall;
- $q_{lr,e}$ is the density of the heat flow rate by long-wave radiation exchanged with the other surfaces of the adjacent room;
- $q_{sr,i}$ is the density of heat flow rate due to absorbed short-wave radiation at the internal surface of the wall (see 4.5.3.2);
- $q_{lr,i}$ is the density of the heat flow rate received by long-wave radiation at the internal surface of the wall from the other internal surfaces (see 4.5.4.2);
- $h_{c,e}$ is the convective heat transfer coefficient at the external surface;
- $h_{c,i}$ is the convective heat transfer coefficient at the internal surface (see Table 1).

4.4.2.2 Ceiling/floor

Referring to Figure 5, the following boundary conditions are considered:

\[
\begin{align*}
\theta_{a,e} &= \theta_{a,i} \\
q_{sr,ec} &= q_{sr,if} \\
q_{lr,ec} &= q_{lr,if}
\end{align*}
\]

Key

1. Similar room
2. Ceiling
3. Room
4. Floor
5. Similar room

Figure 5 - Ceiling/floor adjacent to similar rooms
\[ q_{sr,ef} = q_{sr,ic} \]  
\[ q_{lr,ef} = q_{lr,ic} \]  
\[ h_{c,ec} = h_{c,if} \]  
\[ h_{c,ef} = h_{c,ic} \]

where

\( \theta_{a,e} \) is the air temperature of the adjacent room;

\( \theta_{a,i} \) is the air temperature of the room;

\( q_{sr,ec} \) is the density of heat flow rate due to absorbed short-wave radiation at the external surface of the ceiling;

\( q_{sr,ic} \) is the density of heat flow rate due to absorbed short-wave radiation at the internal surface of the ceiling (see 4.5.3.2);

\( q_{sr,ef} \) is the density of heat flow rate due to absorbed short-wave radiation at the external surface of the floor;

\( q_{sr,if} \) is the density of heat flow rate due to absorbed short-wave radiation at the internal surface of the floor (see 4.5.3.2);

\( q_{lr,ef} \) is the density of the heat flow rate by long-wave radiation by the external surface of the floor with the other external surfaces;

\( q_{lr,if} \) is the density of the heat flow rate by long-wave radiation by the internal surface of the floor with the other internal surfaces (see 4.5.4.2);

\( q_{lr,ec} \) is the density of the heat flow rate by long-wave radiation from the external surface of the ceiling to the other external surfaces;

\( q_{lr,ic} \) is the density of the heat flow rate by long-wave radiation from the internal surface of the ceiling to the other internal surfaces (see 4.5.4.2);

\( h_{c,ec} \) is the convective heat transfer coefficient at the external surface of the ceiling;

\( h_{c,if} \) is the convective heat transfer coefficient at the internal surface of the floor (see Table 1);

\( h_{c,ef} \) is the convective heat transfer coefficient at the external surface of the floor;

\( h_{c,ic} \) is the convective heat transfer coefficient at the internal surface of the ceiling (see Table 1).
4.4.3 Adjacent room with defined value of the air temperature

For each component of the envelope (see Figure 6) the following boundary conditions are considered:

\[ \theta_{a,e} = \theta_{a,d} \]
\[ q_{sr,e} = 0 \]
\[ h_{c,e} = h_{c,i} \]
\[ h_{c,ec} = h_{c,if} \]
\[ h_{c,ef} = h_{c,ic} \]  

(9)

where

- \( \theta_{a,d} \) is the air temperature of the adjacent room;
- \( q_{sr,e} \) is the density of heat flow rate due to absorbed short-wave radiation at the external surface;
- \( h_{c,e} \) is the convective heat transfer coefficient at the external surface of the vertical wall;
- \( h_{c,i} \) is the convective heat transfer coefficient at the internal surface of the vertical wall (see Table 1);
- \( h_{c,ec} \) is the convective heat transfer coefficient at the external surface of the ceiling;
- \( h_{c,if} \) is the convective heat transfer coefficient at the internal surface of the floor (see Table 1);
- \( h_{c,ef} \) is the convective heat transfer coefficient at the external surface of the floor;
- \( h_{c,ic} \) is the convective heat transfer coefficient at the internal surface of the ceiling (see Table 1).
4.4.4 Floor on ground

The heat transfer between the room and the external environment through the ground is calculated as the sum of a steady state component and a monthly variable component as specified in EN ISO 13370. The monthly variable component is treated as one-dimensional and perpendicular to the floor surface. The calculation procedure shall combine this heat flow rate with the thermal storage of the floor construction together with a 0,5 m thick layer of soil beneath it.

NOTE One acceptable way is to introduce a monthly varying boundary temperature at a depth of 0,5 m beneath the floor construction. This boundary temperature is defined so that the heat flow rate from the room air at its mean monthly temperature to the boundary layer equals the heat flow rate to and through the ground calculated according to EN ISO 13370.

4.4.5 Cellar or crawl space

A cellar is considered as an adjacent room with fixed air temperature (see 4.4.2). A crawl space is treated as a floor on the ground according to EN ISO 13370. Boundary conditions are as specified in 4.4.3.

4.4.6 Ceiling below attic

According to the assumptions of 4.2.6.1, the boundary conditions are represented by:

$\theta_{a,e}$ is the external air temperature;

$q_{sr,e}$ is defined by Equation (17) in 4.5.3.1;

$q_{fr,e}$ is defined by Equation (24) in 4.5.4.1.

4.5 Terms in the thermal balance equations

4.5.1 Heat conduction through components

For elements with constant thermal conductivity and specific heat capacity, the density of heat flow by conduction is governed by the following equations:

$$q_n = -\lambda \frac{\partial \theta}{\partial t}$$

(10)

$$\lambda \left( \frac{\partial^2 \theta}{\partial x^2} + \frac{\partial^2 \theta}{\partial y^2} + \frac{\partial^2 \theta}{\partial z^2} \right) + g = c \rho \frac{\partial \theta}{\partial t}$$

(11)

where

$\theta$ is the temperature of the component (in direction of the heat flow) at the time $t$;

$q$ is the density of heat flow rate in direction $n$;

$\lambda$ is the thermal conductivity of the medium;

$c$ is the specific heat capacity of the medium;

$\rho$ is the density of the medium;

$g$ is the heat source term (heat flow rate per volume);

$x, y, z$ are co-ordinates.

These equations may be solved by any appropriate procedure which provides results in accordance with the validation procedure given in Clause 7.
NOTE A suitable procedure is described in Annex A.

4.5.2 Convective heat transfer

4.5.2.1 General
Convective heat transfer occurs at the boundary surfaces of each building element and through air layers.

4.5.2.2 Convective heat flow rate at the surfaces of an element
The density of convective heat flow rate at the internal and external surface of element is given by:

\[ q_c = h_c (\theta_s - \theta_a) \]  \hspace{1cm} (12)

where
- \( h_c \) is the convective heat transfer coefficient of the surface;
- \( \theta_s \) is the surface temperature;
- \( \theta_a \) is the air temperature.

At the external surface the values of the convective heat transfer coefficient \( h_{c,e} \), is given by:

\[ h_{c,e} = 4 + 4v \]  \hspace{1cm} (13)

where
- \( v \) is the wind velocity near the surface.

The wind velocity near the surface, \( v \), depends on the climatic data of the locality and on the envelope characteristics. Unless otherwise specified, the value of 1 m/s shall be used. The values of the convective heat transfer coefficient at the internal surface, \( h_{c,i} \), are given in Table 1.

NOTE The values in Table 1 were determined using the equations given in EN ISO 6946 for the following conditions:
- temperature difference \( (\theta_i - \theta_a) < 10 \) K;
- surface hydraulic diameter = 4,5 m \((4 \times \text{area}/\text{perimeter})\).

The air temperature required in Equation (12) is:
- for internal surfaces: the room air temperature;
- for external surfaces: the conditions given in Table 2.

4.5.2.3 Convective heat transfer through unventilated air layers

The density of convective heat flow rate through an unventilated air layer, \( q_c \), is given by:

\[
q_c = \Lambda_a \Delta \theta
\]

(14)

where

\[
\Delta \theta \quad \text{is the temperature difference between the surfaces delimiting the layer;}
\]

\[
\Lambda_a \quad \text{is the thermal conductance of the air layer.}
\]

The thermal conductance of an unventilated air layer is calculated according to:

— EN ISO 6946 between opaque surfaces;

— EN ISO 10077-1 between transparent surfaces.

NOTE For transparent surfaces, the thermal conductance of an unventilated air layer can be calculated assuming the following reference conditions:

— air density: 1,139 kg/m\(^3\)

— dynamic viscosity: \(1,861 \times 10^{-5}\) kg/(m·s)

— thermal conductivity: 0.0264 W/(m·K)

— specific heat capacity: 1008 J/(kg·K)

— thermodynamic temperature: 300 K

— temperature difference: 5 K.

Table 3 gives some values of thermal conductance, \( \Lambda_a \), for vertical and horizontal unventilated air layers between transparent components. For other thicknesses, thermal conductances may be derived by interpolation.

4.5.2.4 Convective heat transfer through ventilated air layer

The convective heat flow rate through a ventilated air layer, $\Phi_{va}$, depends on the air flow rate in the air layer. The heat flow rates to be considered are:

a) the convective heat flow rate, $\Phi_{va}$, due to air passing through the air layer and into the room, given by:

$$\Phi_{va} = m_{a,v} c_a (\theta_l - \theta_{a,i})$$  \hspace{1cm} (15)

where

$m_{a,v}$ is the mass air flow through the air layer;

$\theta_l$ is the temperature of the air leaving the layer;

b) the convective heat flow rate, $\Phi_{c,j}$, between surfaces and air, given by:

$$\Phi_{c,j} = h_a A_c (\theta_j - \theta_{eq})$$

$$\Phi_{c,j+1} = h_a A_c (\theta_{j+1} - \theta_{eq})$$  \hspace{1cm} (16)

where

$A_c$ is the area of the surface in contact with the air layer;

$h_a$ is the convective heat transfer coefficient for ventilated layers;

$\theta_{eq}$ is the equivalent temperature of the air in the layer;

$j$ and $j + 1$ refer to the surfaces delimiting the air layer.

NOTE A procedure for determining the parameters in Equations (15) and (16) is given in Annex B.
4.5.3 Short-wave radiation heat transfers

4.5.3.1 Short-wave radiation heat transfer at the external surface of opaque element

The density of short-wave radiation heat flow rate at the external surface of an opaque element is given by:

\[ q_{sr,e} = \alpha_{sr} (f_s I_D + I_d) \]  

(17)

where

\( \alpha_{sr} \) is the solar absorptance;

\( f_s \) is the sunlit factor;

\( I_D \) is the direct component of the solar radiation reaching the surface;

\( I_d \) is the diffuse component of the solar radiation reaching the surface.

The values of solar absorptance of external opaque surfaces, \( \alpha_{sr} \), depend on the characteristics of the external surface of the element. Table 4 gives values of the solar absorptance as a function of the colour of the external surface that may be used when no specific values are available.

<table>
<thead>
<tr>
<th>Light colour</th>
<th>Intermediate colour</th>
<th>Dark colour</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \alpha_{sr} )</td>
<td>0,3</td>
<td>0,6</td>
</tr>
</tbody>
</table>

The values of the direct, \( I_D \), and diffuse, \( I_d \), components of the solar radiation reaching the differently oriented surfaces may be derived from national data.

The sunlit factor, \( f_s \), is given by:

\[ f_s = \frac{A_s}{A} \]  

(18)

\( A_s \) is the sunlit area of the wall (defined in 4.5.3.5);

\( A \) is the total area of the wall.

4.5.3.2 Short-wave radiation heat transfer at the internal surface of opaque elements

The density of heat flow rate by short-wave radiation absorbed at the internal surface of an opaque element is given by:

\[ q_{sri} = (1 - f_{sa})(1 - f_{sl})(\Phi_{sr,D} + \Phi_{sr,d})f_d \]  

(19)

where

\( f_{sa} \) is the solar to air factor of the room;

\( f_{sl} \) is the solar loss factor of the room;

\( f_d \) is the distribution factor of the solar radiation at the internal surface of the element;
Φ_{sr,D} is the heat flow rate due to the direct component of solar radiation entering the room;

Φ_{sr,d} is the heat flow rate due of the diffuse component of solar radiation entering the room.

The heat flow rates due to the direct and diffuse components of the solar radiation, entering the room, are given by Equations (20) and (21), respectively:

\[ \Phi_{sr,D} = \sum_{j=1}^{J} (I_D \tau_D A_s)_j \]  

(20)

\[ \Phi_{sr,d} = \sum_{j=1}^{J} (I_d \tau_d A)_j \]  

(21)

where

- \( J \) is the number of glazing components;
- \( I_D \) is the direct component of solar radiation reaching the external surface of the system \( j \);
- \( I_d \) is the diffuse component of solar radiation reaching the external surface of the glazing system \( j \);
- \( \tau_D \) is the direct solar transmittance of the glazing system;
- \( \tau_d \) is the diffuse solar transmittance of the glazing system;
- \( A_s \) is the sunlit area of the glazing (see 4.5.3.5);
- \( A \) is the glazing area.

The direct and diffuse solar transmittance of each glazing system \( \tau_D \) and \( \tau_d \) shall be determined according to EN 410. If no values are available, \( \tau_D \) and \( \tau_d \) shall be calculated at the normal incident angle.
Solar to air factor

The solar to air factor, $f_{sa}$, is the fraction of solar heat entering the room through the glazing which is immediately transferred to the internal air. This fraction depends on the quantity of internal items with very low thermal capacity such as carpets and furniture. It is assumed to be time independent.

Solar loss factor

The solar loss factor, $f_{sl}$, is the fraction of the solar radiation entering the room which is reflected back to the external environment. It depends on the geometrical characteristics and solar properties of the glazing system, the exposure of the glazing, the solar angles and the room geometry and colour of the surfaces. It is assumed to be time independent.

Distribution factors

The distribution factors, $f_d$, define the amount of the direct solar radiation absorbed per area at the different internal surfaces of the walls, ceiling, floor, etc. They depend on the solar angles, the geometrical dimensions of glazing and room, the short-wave reflectance of components, and the furniture and furnishings. It is assumed to be time independent.

NOTE Unless otherwise specified, values of $f_{sa}$, $f_{sl}$ and $f_d$ given in informative Annex G can be used.

4.5.3.3 Short-wave radiation heat flow rate for transparent elements (including blinds and curtains)

Transparent elements partially transmit, reflect and absorb the solar radiation impinging on their external surface. For multi-layered glazed elements (e.g. double pane window with internal and/or external blind) the following solar parameters are required:

— direct and diffuse solar energy transmittance of the system, $\tau_D$ and $\tau_d$;

— equivalent direct and diffuse solar energy absorptance of each component of the glazed element, $\alpha'_{sr}$.

\[
\begin{align*}
q_{sr,eb} &\quad q_{sr,ep} &\quad q_{sr,ip} &\quad q_{sr,ib} \\
I_D &\quad I_d &\quad I_d &\quad I_d \\
\alpha'_{sr,eb} &\quad \alpha'_{sr,ep} &\quad \alpha'_{sr,ip} &\quad \alpha'_{sr,ib} \\
1 &\quad 2 &\quad 3 &\quad 4
\end{align*}
\]

Key

1  External blind (eb)
2  External pane (ep)
3  Internal pane (ip)
4  Internal blind (ib)

Figure 7 – Double pane with internal and external blinds
These solar parameters shall be calculated according to EN 410 taking into account the solar energy transparence and reflectance of each component. If no data are available for various incident angles, values of these parameters at the normal incident angle can be taken as safe values. The density of heat flow rate for element $j$ of the glazing system due to the absorbed solar radiation is then determined as:

$$ q_{sr,j} = \alpha'_{sr,j} (l_D f_s + l_q) $$  \hspace{1cm} (22)

where

- $j$ is the element of the glazing system;
- $\alpha'_{sr}$ is the equivalent solar absorptance.

If curtains or venetian blinds are present, the following situations can occur:

a) curtain/blind completely closed;
b) curtain/blind not completely closed.

In case a) the glazing component and the curtain/blind are treated as a single envelope component having appropriate solar coefficients.

In case b) two different components shall be considered:

- the portion of glazing area not covered by the curtain/blind, comprising the glazing component only;
- the portion of glazing area covered by the curtain/blind, treated as in case a).

### 4.5.3.4 Solar to air heat flow rate

The solar to air heat flow rate, $\Phi_{sra}$, is the heat flow rate due to solar radiation, entering through the glazing system, directly transferred to the internal air. It is given by:

$$ \Phi_{sra} = f_{sa} (1 - f_{sl}) \cdot (\Phi_{sr,D} + \Phi_{sr,d}) $$  \hspace{1cm} (23)

The parameters in Equation (23) are the same as in Equation (19).

### 4.5.3.5 Sunlit area of room element

When external obstructions are present, the area of an element can be partially shaded. Obstructions considered in this document are: horizontal overhangs, side fins, window set back and surrounding constructions. A reduction factor may be added for the diffuse radiation in Equations (16) and (19). For the sake of safety, it may be assumed that:

- the effect of shading is only to reduce the direct solar component;
- the effect of mutual reflections is negligible.

The evaluation of the sunlit area may be obtained by any appropriate procedure that provides results in accordance with the validation tests given in Clause 7.

NOTE A suitable procedure is described in Annex C.

### 4.5.4 Long-wave radiation heat transfer

#### 4.5.4.1 Heat flow rate at the external surface

According to the assumptions of 4.1, the density of net long-wave radiant heat flow rate received by an external surface, $q_{ir,e}$, is given by:
EN ISO 13791:2004 (E)

\[ q_{lr,e} = h_{lr,e}(\theta_{a,e} - \theta_{s,e}) - q_{sk} \]  \hspace{1cm} (24)

where

- \( h_{lr,e} \) is the long-wave radiative heat transfer coefficient;
- \( \theta_{a,e} \) is the external air temperature;
- \( \theta_{s,e} \) is the external surface temperature;
- \( q_{sk} \) is the correction for the long-wave radiation exchanges from the wall to the sky.

Using thermodynamic temperatures \( (T = \theta + 273.15) \), the value of \( h_{lr,e} \) is approximated by:

\[ h_{lr,e} = 4\varepsilon\sigma \left( \frac{T_{a,e} + T_{s,e}}{2} \right)^3 \]  \hspace{1cm} (25)

where

- \( \varepsilon \) is the long-wave emissivity of the surface;
- \( \sigma \) is the Stefan-Boltzmann constant;
- \( T_{a,e} \) is the external air temperature;
- \( T_{s,e} \) is the surface temperature.

According to the assumptions of 4.1, the calculations shall be made with a fixed value of \( h_{lr,e} \).

NOTE 1 The terms of Equation (24) can be calculated with the following conditions:

- emissivity of the external surface \( \varepsilon_{lr,e} = 0.93; \)
- reference temperature \( T_m = \frac{T_{a,e} + T_{s,e}}{2} = 303 \text{ K} \)

Under these conditions, the value of \( h_{lr,e} \), for external surfaces, is 5.5 \text{ W/(m}^2\cdot\text{K)}.

The correction for the long-wave radiation emitted from the element to the sky, \( q_{sk} \), is given by:

\[ q_{sk} = F_{sk} \varepsilon \sigma \left( \frac{T_{a,e} + T_{sk}}{2} \right)^3 (T_{a,e} - T_{sk}) \]  \hspace{1cm} (26)

where

- \( F_{sk} \) is the view factor from the element with the sky (solid angle divided by \( 2\pi \));
- \( T_{a,e} \) is the external air temperature;
- \( T_{sk} \) is the temperature of the sky.

The temperature of the sky depends on the characteristics of the atmosphere and its vapour content. Values of these parameters are fixed at national level.
NOTE 2 If no information is available, the procedure of Annex E can be used for determining the various parameters. Equation (F.2) (valid for clear sky) can be used for determining the temperature of the sky; Equation (F.5) can be used for determining the correction term $q_{sk}$.

### 4.5.4.2 Heat flow rate at the internal surface

The density of net long-wave radiant heat flow rate, $q_{lr}$, received by the internal surface $j$, is given by:

$$q_{lr,j} = \sum_{k=1}^{N} (F_{j,k} J_{lr,k}) - J_{lr,j}$$

where

- $N$ is the number of surfaces delimiting the environment;
- $F_{j,k}$ is the view factor from surface $j$ to surface $k$;
- $J_{lr,j}$ is the long-wave radiosity of the surface $j$;
- $J_{lr,k}$ is the long-wave radiosity of the surface $k$.

$F_{j,k}$ is the mean value, over surface $j$, of a solid angle over which surface $k$ is seen from a point on surface $j$, divided by $2\pi$.

The long-wave radiosity of a surface is the total density of heat flow rate emitted and reflected by this surface, all surfaces being here considered as grey bodies. Thus the long-wave radiosity of surface $j$ is:

$$J_{lr,j} = \rho_j \sum_{k=1}^{N} (F_{j,k} J_{lr,k}) + \varepsilon_j \sigma T_j^4$$

where

- $\rho$ is the long-wave radiative reflectance;
- $\varepsilon$ is the long-wave radiative emittance;
- $\sigma$ is the Stefan-Boltzmann constant.

In order to calculate the long-wave radiant heat flow exchanged by the $N$ different inside surfaces, the radiosity $J_{lr}$ for each surface shall be first determined by solving the $N$ simultaneous equations. The solution of Equation (27) shall be carried out for the various surfaces bounding the room.

Equation (27) may be solved by any appropriate procedure which provides results in accordance with the validation procedure given in Clause 7.

NOTE A suitable procedure is described in Annex F.

### 4.5.4.3 Air layers

The density of long-wave radiative heat transfer through air layers is given by:

$$q_{lr} = \lambda_{lr} \Delta \theta$$

where

- $\Delta \theta$ is the temperature difference between the surfaces delimiting the air layer;
- $\lambda_{lr}$ is the long-wave radiative conductance of the air.
The long-wave radiative conductance is given in:

— EN ISO 10077-2 for an air layer between glazing surfaces;
— EN ISO 6946 for an air layer between opaque layers.

For ordinary surfaces the following values are considered:

— opaque surface \( \varepsilon = 0.93 \) \( \Lambda_{lr} = 5.0 \text{ W/(m}^2\cdot\text{K)} \);
— transparent surfaces \( \varepsilon = 0.837 \) \( \Lambda_{lr} = 4.4 \text{ W/(m}^2\cdot\text{K)} \);
— opaque surface \( \varepsilon = 0.93 \) and transparent surface \( \varepsilon = 0.837 \) \( \Lambda_{lr} = 4.6 \text{ W/(m}^2\cdot\text{K)} \).

### 4.5.5 Internal gains

Internal gains usually derive from lighting, equipment and occupants. The relevant heat flow rate includes a convective component, \( \phi_{i,c} \), and a long-wave radiative component, \( \phi_{i,r} \), which are respectively included in Equations (1) and (2). The total radiative component, \( \phi_{i,r} \), is supposed to be uniformly distributed on all the internal surfaces bounding the room, including windows.

**NOTE** Unless otherwise specified, the heat flow rate values given in Annex H for internal sources can be used.

### 4.5.6 Heat flow due to ventilation

#### 4.5.6.1 General

The net heat flow rate to the room air due to natural and mechanical ventilation is calculated as:

\[
\phi_v = c_a q_a (\theta_{ii} - \theta_{ai})
\]  

(30)

where

- \( c_a \) is the specific heat capacity of the inlet air;
- \( q_a \) is the mass air flow rate;
- \( \theta_{ii} \) is the inlet air temperature;
- \( \theta_{ai} \) is the internal air temperature.

The inlet air temperature depends on its source (e.g. external air or adjacent room). The mass air flow rate results from natural and/or forced ventilation.

#### 4.5.6.2 Natural ventilation

The air flow rate due to natural ventilation depends on the dimensions and type of cracks and openings (including doors and windows), the temperature difference, the wind speed and its direction. It is given by:

\[
m_a = c_d \rho A \left( \frac{2 \Delta p}{\rho} \right)^n
\]  

(31)

where

- \( c_d \) is the coefficient of discharge;
- \( A \) is the area of the opening;
\[ \Delta p \] is the pressure difference between internal and external environments;

\[ \rho \] is the density of the air;

\[ n \] is a coefficient between 0.5 and 1.

The values of coefficients \( c_d \), \( n \) and area \( A \) depend on the position and flow characteristics of all openings. It is assumed that the air in the room is well mixed.

NOTE  Annex J gives a suitable procedure to evaluate the volumetric air flow rate by natural ventilation.

### 4.5.6.3 Mechanical ventilation

The mass air flow rate due to forced ventilation depends on the characteristics of the supply/exhaust system.

## 5 Procedure for carrying out calculations

### 5.1 General

This document is used for calculating the internal temperatures (air and internal surfaces) for the intended purposes given in Clause 1. It should, however, be noted that these "predicted internal temperatures" are determined on the basis of a set of assumptions described in various clauses of this document. Using a different set of assumptions, e.g. boundary conditions or surface coefficients, will lead to a different set of "predicted internal temperatures". Furthermore, the calculations for determining "predicted internal temperatures" shall be carried out according to the procedure and values for the design climate data, design geometric and thermophysical characteristics of the room, and its components, and the design internal gains as defined below.

### 5.2 Design climatic data

#### 5.2.1 General

The calculation method uses time varying values of various climatic data. The time period and the type of climatic data used affect the calculation of internal temperatures. The design climatic data may be given in a national annex to this document according to the following methods:

- long period design climatic data;
- design warm sequence.

#### 5.2.2 Long-period design climatic data

If the internal temperatures are determined from a long period of climatic data, the hourly values of the following are required for the whole of period considered: the value of direct and diffuse solar radiation components on the various facades, the external air temperature, the wind velocity and its prevailing direction. Climatic data may be given in a national annex to this document.

#### 5.2.3 Design warm sequence

Such a sequence of several days shall be chosen so as to be representative of the hottest conditions for a given climate. Because the hottest internal conditions do not necessarily coincide with the warmest external conditions, it may be necessary to consider the different climatic situations for several months. For each month, the design warm sequence shall be defined by:

- hourly values of direct and diffuse (sky and ground reflected) components of solar radiation on the various facades;
- hourly values of the external air temperature;
5.3 Geometrical and thermophysical characteristics of room elements

The appropriate boundary conditions are given in 4.4. For each element the following properties shall be provided:

a) geometrical properties: width and height (or length and width) of each component measured from the internal surfaces;

b) thermophysical properties: thermal conductivity, density and specific heat of each layer of layered elements and thermal resistance of air gaps and window/blind thermal characteristics.

5.4 Design internal gains

Internal gains are generally due to occupants, equipment and lights. These contributions vary with occupant behaviour. Design internal gains may be given in a national annex to this document.

NOTE Annex H gives data which can be used unless other data are available.

5.5 Design occupant behaviour

Occupant behaviour greatly modifies the internal conditions of a room. The occupants influence the amount of internal heat sources, natural ventilation, and blind arrangements. The reference behaviour to introduce in the "design" calculation may be defined from national data. For a design calculation, the time of opening and closing of a window, the area of opening and the type of blind, shall be fixed.

Design occupant behaviour may be given in a national annex to this document.

5.6 Calculation procedure

5.6.1 General

The internal temperatures are determined by applying the calculation procedure defined in 4.4 and 4.5, considering the climatic data (see 5.2), the geometrical and thermophysical characteristics of the room elements (see 5.3), the internal gains (see 5.4), the occupant behaviour (see 5.5), and the starting conditions defined below. The calculation procedure involves the two consecutive steps:

a) evaluation of the starting conditions;

b) evaluation of the design internal conditions.

5.6.2 Definition of the starting conditions

If the long-period design climatic data are used, the calculation shall be carried out for at least two weeks and the resulting conditions shall be used as the starting conditions. If the design warm sequence is used, the starting conditions are obtained by repeating the calculation given in 4.2 and 4.3 for the mean monthly values of the wind velocity and its prevailing direction.
climatic data defined in 5.2.3, until the predicted internal air temperature over two consecutive days differs by less than 0.01 K. These conditions are then used as the starting conditions.

5.6.3 Prediction of the internal temperatures

The internal temperatures are determined using, as initial conditions, the internal conditions evaluated in 5.6.1. For long-period design climatic data, the internal temperatures are determined hour by hour by considering climatic data defined in 5.2.2. For the design warm sequence, the internal temperatures are determined by iterating the procedures in 4.2 and 4.3, using the climatic data corresponding to the design warm sequence. The number of days depends on the characteristics of the local climatic data. The hourly values of the internal temperature shall be calculated as the average over each hour.

6 Report of the calculation

The calculation report shall include the input data adopted and the results of the calculation.

a) Input data:

— climatic data (hourly values of the external air temperature and solar radiation intensity);
— building characteristics: description of the building and of the rooms investigated;
— volume of room;
— for each element bounding the room:
  opaque elements: area, exposure, thermophysical properties of each layer;
  glazed elements: area, exposure, thermophysical and solar characteristics of each glazed element.

Local clock time shall be used for all time-dependent input data with the exception of climatic data. If the climatic data time convention is different from local clock time, the difference shall be reported.

b) Results:

— hourly values of the air ventilation flow rate (number of changes per hour);
— hourly values of the heat flow rate for internal sources (watts per square metre of floor area);
— hourly values of air temperature and mean radiant temperature.

The predicted temperatures shall be reported for the calculation period and not for the pre-conditioning period.

7 Validation procedures

7.1 Introduction

This document does not impose any specific numerical technique for the calculation of internal temperatures of a single room. The annexes give procedures for the calculation of the different parameters necessary for determining the internal temperature, according to the assumptions included in this document.

Any existing or new numerical solution which claims conformity with this document shall be validated with the tests in this section and be in agreement with the procedures and assumptions.

The results provided by any numerical solution model shall be within the range indicated for each test. The validation procedures refer both to each relevant heat transfer process and to the whole solution model.

NOTE The check of existing or new solution models can be made by the producers of the numerical solution models as well as the producers of computer programs.
7.2 Validation of heat transfer processes

7.2.1 General

Checks shall be made of the following processes:

a) heat conduction through opaque elements;

b) internal long-wave radiation heat exchanges;

c) evaluation of short-wave radiation heat transfer (calculation of shaded area of a window due to external obstructions).

7.2.2 Heat conduction through opaque elements

This procedure requires the evaluation of the internal air temperature of the room specified below at several time intervals.

a) Characteristics of the room:

— internal dimensions 1 m × 1 m × 1 m;

— all elements, including ceiling and floor, are identical with the same boundary conditions;

— the short-wave radiative heat transfer is assumed to be zero;

— the air flow rate due to the ventilation is assumed to be zero;

— the internal convective heat transfer coefficient of each element, including ceiling and floor, is \( h_{c,i} = 2.5 \text{ W/(m}^2\text{K}) \);

— the external convective heat transfer coefficient of each element, including ceiling and floor, is \( h_{c,e} = 8 \text{ W/(m}^2\text{K}) \);

— the emissivities of the internal and external surface of each element, including ceiling and floor, are assumed to be zero (the long-wave radiative heat transfer on the internal and external surfaces are assumed to be zero);

— the thermal capacity of the room air is assumed to be zero.

b) Boundary conditions:

— the external air temperature is variable according to Figure 8:

\( t \leq 0 \): \( \theta_{a,e} = 20 \degree \text{C} \); for \( 0 < t \leq 1 \) (hour): linear variation of the external temperature \( \theta_{a,e} \) from 20 °C to 30 °C; \( t > 1 \) h: \( \theta_{a,e} = 30 \degree \text{C} \);

the internal air temperature \( \theta_{a,i} \) is constant at 20 °C for \( t \leq 0 \).
Key
1  Linear variation of the external temperature

Figure 8 - Variation of the external air temperature

Data to be calculated: the internal air temperature shall be determined after the following times:

a) 2 h; b) 6 h; c) 12 h; d) 24 h; e) 120 h

Tests shall be conducted for the room elements given in Table 5.

### 7.2.3 Internal long-wave radiation exchanges

The validation procedure is based on the calculation, in steady-state conditions, of the internal air temperature of various rooms having opaque walls, and adjacent to spaces with different external air temperatures. Referring to the various tests below indicated, the thermal conductance of surface No.2 (external wall) is $\lambda = 5,0 \text{ W/(m}^2\text{K)}$; the thermal conductance of the other walls (partition vertical walls, ceiling and floor) is $\lambda = 1,0 \text{ W/(m}^2\text{K)}$. The room geometries for the various tests are given in Table 7, and Figures 9a, 9b, 9c and 9d.

**Table 7 - Room geometry**

7.2.4 Sunlit area of a window due to external obstructions

The validation procedure requires the evaluation of the sunlit factor $f_s$ defined in Equation (18) as the ratio between the sunlit area of the plane surface and its total area, for the following tests:

- **Test No. 1**: South orientation - see Figure 10a: overhang;
- **Test No. 2**: South orientation - see Figure 10b: side fins;
- **Test No. 3**: South orientation - see Figure 10c: overhang + side fins;
- **Test No. 4**: South orientation - see Figure 10d: external obstruction;
- **Test No. 5**: East orientation - see Figure 10e: overhang + side fins;
- **Test No. 6**: East orientation - see Figure 10f: external obstruction.
Figure 10a - Test No. 1: South orientation
Figure 10b - Test No. 2: South orientation
Figure 10c - Test No. 3: South orientation
Figure 10d - Test No. 4: South orientation
The hourly solar angles to be used for the tests are determined at each 30 min and reported in Table 10.

<td>61,51</td>
<td>0,0</td>
</tr>
</tbody>
</table>

The solar azimuth angle of Table 10 is eastwards from South, i.e. 0° at south, positive to the east and negative to the west.

For each test, the sunlit factor $f_s$ shall be determined at the following times:

7:00 a.m.; 7:30 a.m.; 8:00 a.m.; 8:30 a.m.; 9:00 a.m.; 9:30 a.m.; 10:00 a.m.; 10:30 a.m.; 11:00 a.m.; 11:30 a.m.; 12:00 noon.

The validation requires to check the values of the sunlit factor at each hour or at each half hour according to the characteristics of the solution model adopted. Each value of $f_s$ shall not differ from those in Table 11 by more than 0,05. Negative values are not consistent.

### 7.3 Validation procedure for the whole calculation method

#### 7.3.1 General

Whole model validation considers the calculation of the operative temperature under cyclic conditions for several cases indicated below, and the comparisons of these values with those included in Table 21 and Table 22. According to the assumptions of 4.1, the operative temperature is calculated as the average of the internal air temperature and the mean radiant temperature. According to the assumptions of this document, the operative temperature is calculated as the average of the internal air temperature \( \theta_{a,i} \) and the mean radiant temperature \( \theta_{mr} \) of the internal surface of the room elements, calculated as:

\[
\theta_{mr} = \frac{\sum_{j=1}^{N} (\theta_{s,i} A_j)}{\sum_{j=1}^{N} A_j}
\]  

(32)

where

- \( N \) is the number of surfaces delimiting the internal space;
- \( \theta_{s,i} \) is the internal surface temperature;
- \( A_j \) is the area of surface \( j \).

The geometrical characteristics of the rooms are given in Table 12.

For determining the thermal capacity of the internal air, the following parameters are used:

— specific heat capacity of air: 1008 J/(kg K)
— air density: 1,139 kg/m³

7.3.2 Geometry for the test rooms

The various test cases refer to two different geometries (Figure 11 and Figure 12) located in two zones with three different types of envelope and ventilation.

Figure 11 - Geometry A
7.3.3 Thermophysical properties of opaque walls

The thermophysical characteristics of the walls, ceiling and floor are given in Table 13.

7.3.4 Properties of glazing

The solar characteristics of the glass panes composing the glazing panes and the external shade are given in Table 14. This table shall be used for computer programs that need these data to calculate the values in Figure 13 and Figure 14.

Window specifications are given in Figures 13 and 14; the thermal resistance of window pane glass is assumed to be zero.

7.3.5 Solar parameters

The solar parameters to be used are the following:

solar to air factor \( f_{sa} = 0.10; \)

solar loss factor \( f_{sl} = 0.00; \)
solar distribution factor:
floor  \( f_d = 0.5 \);
ceiling  \( f_d = 0.1 \);

total vertical walls (excluding windows)  \( f_d = 0.4 \);
ceiling  \( f_d = 0.1 \);

total vertical walls (excluding window)  \( f_d = 0.4 \);
solar absorptance of all wall surfaces  \( \alpha_{sr} = 0.6 \);
solar absorptance of the roof  \( \alpha_{sr} = 0.9 \).

7.3.6 Boundary conditions

External convective heat transfer coefficient  \( h_{c,e} = 8.0 \, \text{W/(m}^2\cdot\text{K)} \);

Internal convective heat transfer coefficient  \( h_{c,i} = 2.5 \, \text{W/(m}^2\cdot\text{K)} \) (horizontal heat flow);

\[ h_{c,i} = 5.0 \, \text{W/(m}^2\cdot\text{K)} \] (upward heat flow);
\[ h_{c,i} = 0.7 \, \text{W/(m}^2\cdot\text{K)} \] (downward heat flow);

Radiative heat transfer coefficient  \( h_{r,e} = 5.5 \, \text{W/(m}^2\cdot\text{K)} \) (all surfaces).

(valid for  \( \varepsilon = 0.93 \) and  \( T_{mr} = 303 \, \text{K} \))

The climatic data are given:

— solar radiation:
  Table 15a – Latitude 40° N is for geometry A;
  Table 15b – Latitude 52° N is for geometry B;

— external air temperature:
  Table 16a and Figure 15 for geometry A;
  Table 16b and Figure 16 for geometry B.

Figure 15 - External air temperature for latitude 40°, in °C
The values of the temperatures and solar radiation reported in the previous tables correspond to instantaneous values at each hour. If time intervals less than one hour are considered, the solar radiation at each time step shall be determined by linear interpolation between the previous and subsequent hour (see the example in Figure 17).

7.3.7 Internal energy sources

The total heat flow rate due to internal sources expressed in watts per square metre of floor area is given in Table 17 and in Figure 18. The heat flow is transferred to the room by convection and radiation in equal proportions (50% for each).

7.3.8 Ventilation

Three different ventilation patterns are considered (Table 18):

a) air changes/h equal to 1 h⁻¹, constant;

b) air changes/h equal to 0,5 h⁻¹, constant from 6:00 a.m. to 18:00 p.m. (inclusive) - other hours air changes/h equal to 10 h⁻¹, constant;

c) air changes/h equal to 10 h⁻¹, constant.

7.3.9 Descriptions of the validation tests

The following tests are considered.

For geometry A (see Figure 11), three tests shall be carried out as shown in Table 19, where the types of elements are identified by the numbers used in Table 13 and the letters used in Figure 13.

Single pane glazing with external shade completely closed exposed to West.

Area of external opaque wall 6,58 m²

Area of window 3,50 m²
Table 19 - Test cases A

7.3.10 Results of validations

For each test the following data, determined in cyclic conditions, shall be calculated:

— daily maximum value of the operative temperature \( \theta_{op,max} \)
— daily average value of the operative temperature \( \theta_{op,av} \)
— daily minimum value of the operative temperature \( \theta_{op,min} \)

For each case the comparison with the values reported in Table 21 for geometry A and Table 22 for geometry B, shall give a difference of less than 0.5 K.

NOTE More detailed information is given in Annex K.
Annex A  
(informative)

Example of solution technique

A.1 Introduction

This annex gives a numerical method for the calculation of the internal temperature of a room in the absence of any cooling plant based on an implicit empirical technique.

A.2 Basic assumptions for the calculation method

The method is based on the assumptions given in 4.1 of this document. Further assumptions on the physical phenomena and on the solution techniques, in order to obtain a simpler energy balance, are introduced. They are:

- energy flows by long-wave radiation to/from each surface are calculated by reference to the effective mean radiant temperatures of the other surfaces, the latter being calculated by area-weighting. The fictitious Mean Radiant Temperature Node is considered as the central node of the network of all long-wave radiative heat transfers;
- the air temperature difference influencing the air flow by infiltration and/or ventilation is assumed to be constant during the time interval.

A.3 Calculation procedure

A.3.1 General

The method operates as follows:

a) it subdivides the system into nodes placed at pre-selected points of interest throughout the system to be simulated;

b) for each node in turn and in terms of all surrounding nodes which are in thermal contact, the governing differential equation is replaced by an implicit numerical approximation, based on the fact that half the sum of the net heat flow rate at the start and finish of any finite time increment is equated with the total rate of change in internal energy in the region represented by the node in question;

c) the resulting set of equations (one for each node) is solved simultaneously at each time step.

A.3.2 Evaluation of the temperature of each enclosure component

A.3.2.1 General

According to Clause 4 sets of equations are written for all nodes characterizing the component. For an opaque wall, in which thermal storage effects occur, a subdivision according to the finite difference technique is introduced. To achieve more accurate computations, homogeneous elements can be subdivided and specified in parts. For transparent components, in which thermal storage effects can be neglected, nodes are chosen according to the characteristics of the component.

For each node (from \( n = 1 \), at the external surface, to \( n = N \), at the internal surface) the equation, deriving from the thermal balance at time \( t + \Delta t \), is written in the general form:

\[
K_{1,n} \theta_{n-1,t+\Delta t} + K_{2,n} \theta_{n,t+\Delta t} + K_{3,n} \theta_{n+1,t+\Delta t} = D_n
\]  

(A.1)
EN ISO 13791:2004 (E)

where factors $K$ depend on the characteristics of the element, and $D$ depends on the state of the system. The temperature of node $n$ at time $t + \Delta t$ is calculated as:

$$\theta_{n,t+\Delta t} = C_n$$

(A.2)

$$\theta_{n,t+\Delta t} = C_n - \frac{K_{3,n} \theta_{n+1,t+\Delta t}}{B_n}$$

(A.3)

where the coefficients $C_n$ ($n = 1, N$), $B_n$ ($n = 1, N$) and $D_n$ ($n = 1, N$) are determined as follows:

$$B_n = K_{2,n} - \frac{K_{1,n} K_{3,n-1}}{B_{n-1}}$$

(A.4)

with $B_1 = K_{2,n}$

$$C_n = \frac{D_n - K_{1,n} C_{n-1}}{B_n}$$

(A.5)

with $C_1 = \frac{D_1}{K_{2,1}}$

The values $B_n$ and $C_n$ are determined with increasing subscript $n$ for all nodes. The required temperature distribution is computed with decreasing subscript $n$. The nodes at the external surface ($n = 1$) and the internal surface ($n = N$) are included within the wall.

A.3.2.2 Coefficients in Equation (A.1)

A.3.2.2.1 Opaque components

With respect to the conflicting requirements imposed by the considerations of good accuracy as well as high speed and low cost of computation, the subdivision of the component into different nodes should be carefully considered. Three nodes per element (layer), with one node placed at each boundary of the element and one at the centre plane, is the minimum nodal representation. To achieve more accurate computations, homogeneous elements can be divided into more parts as follows:

a) limit the distance between two subsequent nodes ($\Delta x$) as a function of the thermal conductivity of the layer:

- if $\lambda < 0.5 \text{ W/(m·K)}$ $\Delta x_{\text{max}} = 0.02 \text{ m}$;
- if $\lambda > 0.5 \text{ W/(m·K)}$ $\Delta x_{\text{max}} = 0.03 \text{ m}$;

b) the time increment $\Delta t$ is determined as: $\Delta t = \Delta x^2/(2a)$

where $a = \lambda/(\rho c)$ is the thermal diffusivity, in $\text{m}^2/\text{s}$.

c) for multilayered constructions, the distance between two subsequent nodes should be calculated for each layer separately. The time increment to be used for the calculation corresponds to the maximum calculated for each layer.

NOTE This nodal representation scheme implies that multilayered construction nodes situated at the boundary between different homogeneous elements represent mixed thermal property regions. Furthermore the internal and external surface nodes, which represent convective, radiative and conductive heat exchanges, have associated thermal capacities equal to one half of the surface layer capacity.

For each node type of interest the factors $K$ and $D$ are derived as follows:

a) Node at the centre of homogeneous elements
EN ISO 13791:2004 (E)

\[ K_{1,n} = -F_n \quad K_{2,n} = 2 (1 + F_n) \quad K_{3,n} = -F_n \quad (A.6) \]

\[ D_n = F_n \theta_{n-1,t} + 2(1-F_n)\theta_{n,t} - F_n \theta_{n+1,t} + B_n (q_{n,t+\Delta_t} + q_{n,t}) \quad (A.7) \]

with

\[ F_n = \frac{\lambda_n \Delta t}{\rho_n c_n \Delta x^2} \quad (A.8) \]

\[ B_n = \frac{\Delta t}{\rho_n c_n \Delta x_n} \]

where

\( \Delta t \) is the time increment;

\( c \) is the specific heat of the region;

\( \Delta x \) is the thickness of the region represented by node \( n \);

\( \lambda \) is the thermal conductivity of the element;

\( \rho \) is the density of the element;

\( q \) is the density of heat flow rate generated within the region.

b) Node situated at the boundary between two different homogeneous elements

\[ K_{1,n} = -F_{n-1} \quad K_{2,n} = (2 + F_{n-1} + F_{n+1}) \quad K_{3,n} = -F_{n+1} \quad (A.9) \]

\[ D_n = F_{n-1} \theta_{n-1,t} + (2 - F_{n-1} - F_{n+1})\theta_{n,t} + F_{n+1} \theta_{n+1,t} + B_n (q_{n,t+\Delta t} + q_{n,t}) \quad (A.10) \]

where suffices \( n-1 \) and \( n+1 \) refer to the homogeneous elements on either side of boundary node \( n \).

\[ F_{n-1} = \frac{\lambda_{n-1} \Delta t}{\Delta x_{n-1}[\rho c \Delta x/2]_{n-1} + (\rho c \Delta x/2)_{n+1}} \quad (A.11) \]

\[ F_{n+1} = \frac{\lambda_{n+1} \Delta t}{\Delta x_{n+1}[\rho c \Delta x/2]_{n-1} + (\rho c \Delta x/2)_{n+1}} \]

\[ B_n = \frac{\Delta t}{\Delta x_{n+1}[(\rho c \Delta x/2)_{n-1} + (\rho c \Delta x/2)_{n+1}]} \quad (A.12) \]

c) Node situated at the boundary between a homogeneous element and an air layer

The node \( n-1 \) is on the opposite side of the air layer.

\[ K_{1,n} = -F_a \quad K_{2,n} = (3/4 + F_a + F_n) \quad K_{3,n} = 1/4 - F_a \quad (A.13) \]
EN ISO 13791:2004 (E)

\[ D_n = F_a \theta_{n-1,t} + (3/4 - F_a - F_n)\theta_{t,t} + (1/4 + F_n)\theta_{n,t} + B_n(q_{n,t+\Delta t} + q_{n,t}) \]  
(A.14)

with

\[ F_a = \frac{A_a + A_l}{\rho_n c_n \Delta x} \quad F_n = \frac{2A_n \Delta t}{\rho_n c_n \Delta x^2} \quad B_n = \frac{2h_l \Delta t}{\rho_n c_n \Delta x_n} \]  
(A.15)

where

\[ \Delta x \] is the distance between two subsequent nodes;
\[ A_l \] is the long wave radiative conductance of the cavity;
\[ A_a \] is the air conductance;

Subscript l refers to air layer.

In the Equation (A.15) the air conductance is determined by using the values of Table 3 or Table 4 or for an unventilated air cavity, or by \( q_{c,n}/(\theta_n - \theta_t) \) (see annex B) for a ventilated air cavity; the radiative conductance of the cavity is calculated according to 4.5.4.3, Equation (29).

d) Node at the external surfaces of a room element (\( n = 1 \))

\[ K_{1,1} = 0 \quad K_{2,1} = 3/4 + F_1 + F_e \quad K_{3,1} = 1/4 - F_1 \]  
(A.16)

\[ D_1 = (3/4 - F_e - F_1)\theta_{t,t} + F_e (\theta_{ae,t+\Delta t} + \theta_{ae,t}) + (1/4 + F_1)\theta_{2,t} + B_1(q_{1,t+\Delta t} + q_{1,t}) \]  
(A.17)

with \( F_e = h_{c,e} \Delta t/(\rho_1 c_1 \Delta x_1) \) and \( q = q_{sre} - q_{er} \)

where

\( \theta_{ae} \) is the air temperature of the adjacent space;
\( h_{c,e} \) is the external convective surface coefficient of heat transfer (see Equation 14);
\( q_{sre} \) is the density of total solar heat flow rate absorbed at the external surface;
\( q_{er} \) is the density of long wave radiative heat flow rate to the vault sky.

e) Node at the internal surfaces of a room element (\( n = N \))

\[ K_{1,N} = 1/4 - F_N \quad K_{2,N} = (3/4 + F_N + F_i) \quad K_{3,N} = 0 \]  
(A.18)

\[ D_N = (1/4 + F_N)\theta_{N-1,t} + (3/4 - F_e - F_N)\theta_{N,t} + F_e (\theta_{ai,t+\Delta t} + \theta_{ai,t}) + B_N(q_{N,t+\Delta t} + q_{N,t}) \]  
(A.19)

with \( F_i = h_{c,i} \Delta t/(\rho_N c_N \Delta x_N) \) and \( q = q_{in} - q_{sri} \)

where

\( \theta_{ai} \) is the room air temperature;
\( h_{c,i} \) is the internal convective surface coefficient of heat transfer (see Table 1);
\( q_{in} \) is the density of net heat flow rate due to long-wave radiation received by the internal surface (see Annex E);
\( q_{sri} \) is the density of heat flow rate due to short wave radiation absorbed by the internal surface (see Equation (19)).
A.3.2.2.2 Transparent components

The following equations refer to a transparent component formed by a double pane of glass. In this component, neglecting the thickness of each glass pane, the following nodes are present:

— node at the external pane (external surface);
— node at the internal pane (internal surface);
— node in the air cavity between the panes.

This situation can be extended to consider internal and external blinds. One single pane without any blind can be considered by assuming the value of the heat transfer coefficient between each pane very high.

**a) Node \((n = 1)\) located at the external surface**

\[
K_{1,1} = 0 \quad K_{2,1} = h_{c,e} + \Delta t \quad K_{3,1} = -\Delta t \\
D_1 = h_{c,e} \Delta t + (q_{sr,e} - q_{er}) t + \Delta t \tag{A.20}
\]

**node \((n = N)\) located at the internal surface**

\[
K_{1,N} = -\Delta t \quad K_{2,N} = h_{c,i} + \Delta t \quad K_{3,N} = 0 \\
DN = h_{c,i} \Delta t + (q_{lr,i} + q_{sr,i}) t + 1 \tag{A.22}
\]

Where

- \(h_{c,e}\) is the external convective heat transfer coefficient (from Equation (13));
- \(h_{c,i}\) is the internal convective heat transfer coefficient (from Table 1);
- \(\Delta t\) is the sum of the gas conductance and the radiative conductance of the cavity;
- \(q_{sr}\) is the density of the short-wave radiant heat flow absorbed by the surface;
- \(q_{lr}\) is the density of the long-wave radiant heat flow absorbed by the surface.

**b) Node \(n\) located between and two air layers**

\[
K_{1,n} = -\Delta t, n - 1 \quad K_{2,n} = \Delta t, n + 1 + \Delta t, n - 1 \quad K_{3,n} = -\Delta t, n + 1 \tag{A.24}
\]

\[
D_n = q_{n,i} t + \Delta t \tag{A.25}
\]

Where

- \(\Delta t\) is the sum of the air conductance and the long-wave radiative conductance \(\Delta t\);
- \(q_{n}\) is the density of the radiant heat flow absorbed by the surface.

A.3.2.3 Air temperature

The air temperature is determined by solving the following equation:

\[
\sum_{j=1}^{N} K_{1,j} \theta_{N,t+\Delta t},j + K_{2,a} \theta_{a,t+\Delta t} = D_a \tag{A.26}
\]
EN ISO 13791:2004 (E)

with

\[ K_{2a} = 2 + \left[ \sum_{j=1}^{N} (h_{c,i,j} A_j) + (c_a q_n + c_a q_m) \right] / C_a \]

\[ D_a = \left[ \sum_{j=1}^{N} (h_{c,i,j} A_j) / C_{a,j} + (\phi_{a,t+\Delta t} + \phi_{a,t}) / C_{a,j} \right] + \right. \]

\[ + \left. \left\{ 2 - \left[ \sum_{j=1}^{N} (h_{c,i,j} A_j) + c_a q_n + c_a q_m / C_{a,j} \right] \right\} \theta_{a,i,t} + \right. \]

\[ + [c_a q_n (\theta_{ae,t+\Delta t} + \theta_{ae,t}) + c_a q_m (\theta_{v,t+\Delta t} + \theta_{v,t}) / C_{a,j}] \]

(A.27)

where

\( N \) is the number of enclosure surfaces;
\( h_{c,i,j} \) is the convection coefficient at each internal surface \( j \);
\( A \) is the area of each surface at each internal surface \( j \);
\( q_n \) is the mass air flow rate by natural ventilation;
\( q_m \) is the mass forced air flow rate by mechanical ventilation;
\( c_a \) is the specific heat capacity of the air;
\( \theta_{a,e} \) is the external air temperature;
\( \theta_{a,i} \) is the internal air temperature;
\( \theta_v \) is the temperature of the mechanically supplied air;
\( C_a = \frac{\rho_a c_a V}{\Delta t} \) (A.28)

where
\( \rho_a \) is the density of air;
\( V \) is the enclosure volume;
\( \Delta t \) is the time increment.

The terms \( \Phi_a \) are summations of the convective energy exchanges with the enclosure air at any time \( t \) and \( t + \Delta t \). In general form this is given by:

\[ \Phi_a = \Phi_{i,c} + \Phi_{air} + \Phi_{sa} \] (A.29)

where
\( \Phi_{i,c} \) is the heat flow rate due to the convective component of internal gains;
\( \Phi_{air} \) is the heat flow rate due to the air passing through internal air cavities;
\( \Phi_{sa} \) is the heat flow rate due to the convective part of solar radiation flow entering through the window.

The heat flow rate due to the convective component of internal gains acting at the enclosure air point (room air) is given by:

\[ \Phi_{i,c} = \sum_{j=1}^{m} \Phi_{i,j} f_{i,c,j} \] (A.30)

where
\( m \) is the number of different sources;

\( \Phi_i \) is the heat flow rate due to each internal source \( j \);

\( f_{i,c} \) is the fraction of the total heat flow rate due to each internal source \( j \).

The data of internal gains in annex H can be considered.

The mass air flow by natural ventilation can be calculated according to the procedure in annex H.

The convective part of the short-wave radiation entering through the glazing system, is given by Equation (22):

\[
\Phi_{\text{sra}} = f_{sa} (1 - f_H) (\Phi_{\text{sr,D}} + \Phi_{\text{sr,d}})
\]  
(A.31)

**A.4 Room thermal balance**

Equation (A.1), written for all internal surfaces, with Equation (A.26) written for the internal air, are simultaneously solved. From the solution of the system equations, the internal surface temperature of each enclosure component and the internal air temperature are determined. The required temperature distribution within each component is determined by using Equation (A.2) with decreasing subscript \( n \).
Annex B
(informative)

Convective heat transfer through ventilated air layer

B.1 Introduction

The procedure presented in this annex allows the user to determine the convective heat transfer through a vertical and externally ventilated air layer. An example is the air gap between a glass pane and a curtain where openings are present around the curtain and the curtain itself may be partially permeable to the air flow.

B.2 Convective heat transfer for a vertical air layer

For a vertical ventilated air layer the convective heat transfer is:
— with the environment due to the air flow through the air cavity;
— with the boundary surfaces.

These require the evaluation of the air velocity within the cavity.

B 2.1 General

B 2.1.1 Evaluation of the outlet velocity of the vertical air layer

The mean velocity of the air in the space is principally caused by the stack effect. Convection caused by wind pressure is neglected.

The mean air velocity depends on the driving pressure difference, $\Delta p_m$, and on the total pressure loss in the ventilated air space itself (Figure B.1).

Figure B.1 - Example of vertical air layer: the height of the neutral plane depends on the flow resistances of the inlet and outlet openings

Key
1 Layer $n - 1$
2 Layer $n$
3 Top
4 Neutral plane
5 Bottom
The driving pressure difference results from the temperature difference between the air layer and the air of the environment. It is written as:

$$\Delta \rho_m = \rho_0 \ g \ T_0 \ H (T_{eq} - T_{ext}) / (T_{eq} - T_{ext})$$  \hspace{1cm} (B.1)$$

with

$$T_{eq} = T_{av} - E_{r} (T_{av} - T_{ext}) (1 - e^{-1/E_{r}})$$  \hspace{1cm} (B.2)$$

$$T_{av} = (T_{n-1} + T_{n}) / 2$$  \hspace{1cm} (B.3)$$

$$E_{r} = [(\rho \ c_p \ d_a) / (2 \ h_{a} \ H)] \ \nu$$  \hspace{1cm} (B.4)$$

$$h_{a} = 2 \ h_{g} + c_v \ \nu$$  \hspace{1cm} (B.5)$$

where

- $\Delta \rho_m$ is the driving pressure difference, in Pa;
- $\rho_0$ is the density of the air at the temperature $T_0$, in kg/m$^3$;
- $H$ is the height of the element, in m;
- $T_0$ is the reference temperature;
- $T_{eq}$ is the equivalent temperature of the air in the layer, in K;
- $T_e$ is the temperature of the environment, external or internal air, in K;
- $T_{av}$ is the average of temperatures of the surfaces delimiting the air layer, in K;
- $T_{n-1}$, $T_{n}$ are the temperature of the layer $n - 1$ and $n$;
- $E_{r}$ is a ventilation parameter;
- $c_p$ is the specific heat of the air at the constant pressure, in J/(kg⋅K);
- $d$ is the width of the air layer between the delimiting surfaces, in m;
- $\nu$ is the mean velocity in the ventilated air layer, in m/s;
- $h_{g}$ is the convective heat transfer coefficient for closed spaces, in W/(m$^2$⋅K);
- $c_v$ is the velocity coefficient, in W⋅s/(m$^3$⋅K);
- $g$ is the acceleration due to gravity (constant) 9.81 m/s$^2$.

The coefficient $h_{g}$ can be calculated with the following equation:

$$h_{g} = [\lambda \ A \ (Ra)^n] / s$$  \hspace{1cm} (B.6)$$

where, for vertical spaces: $A = 0.035$; $n = 0.38$ and the Rayleigh number is:

$$Ra = \frac{g \ s^3 \ c_p \ \rho^2 \ |T_j - T_{j+1}|}{\mu \ A \ T_{av}}$$  \hspace{1cm} (B.7)$$

where

- $\mu$ is the dynamic viscosity of the gas in the air layer, in kg/(m⋅s);
- $\lambda$ is the thermal conductivity of the gas in the air layer, in W/(m⋅K);
- $\rho$ is the density of the gas in the air layer.
The velocity coefficient \( c_v \) can be assumed equal to \( 4 \text{ W} \cdot \text{s/(m}^3 \cdot \text{K}) \).

The total pressure loss \( \Delta p_T \) in the ventilated air layer is calculated as:

\[
\Delta p_T = \Delta p_v + \Delta p_d + \Delta p_{io}
\]  
(B.8)

where

- \( \Delta p_v \) is the kinetic pressure loss, in Pa;
- \( \Delta p_d \) is the pressure loss due to the steady laminar flow, in Pa;
- \( \Delta p_{io} \) is the pressure loss in the top and bottom openings, in Pa.

The terms in Equation (B.8) are given by:

\[
\Delta p_v = \frac{1}{2} \rho v^2
\]  
(B.9)

\[
\Delta p_d = 8 \mu \frac{H}{s^2} v
\]  
(B.10)

\[
\Delta p_{io} = \frac{1}{2} \rho v^2 (Z_1 + Z_2)
\]  
(B.11)

where

- \( \mu \) is the dynamic viscosity of the air, in kg/(m \cdot s);
- \( v \) is the velocity of the air within the cavity, in m/s;
- \( H \) is the height of the cavity, in m;
- \( d \) is the width of the cavity, in m;
- \( Z_1, Z_2 \) are parameters relevant for the top and bottom openings.

The parameters \( Z_1 \) and \( Z_2 \), according to Figure B.2, are given by:

\[
Z_1 = \left( \frac{A_s}{0.6 A'_1} - 1 \right)^2
\]  
(B.12)

\[
Z_2 = \left( \frac{A_s}{0.6 A'_2} - 1 \right)^2
\]  
(B.13)

\[
A'_1 = A_b + \frac{A_t + A_v + A_h}{4}
\]  
(B.14)

\[
A'_2 = A_t + \frac{A_l + A_v + A_h}{4}
\]  
(B.15)
Figure B.2 - Example of ventilated cavity

The velocity \( v \) in the ventilated air layer is obtained by solving the following:

\[
\Delta \rho_m = \Delta \rho_T \tag{B.16}
\]

### B.2.1.2 Evaluation of the convective heat transfers for a vertical air layer

The convective heat flow rates \( \Phi \) are calculated as:

— due to the air motion:

\[
\Phi_v = m_v \ c_p \ (T_{out} - T_{in}) \tag{B.17}
\]

where

- \( m_v \) is the mass air flow through the air layer, in kg/s;
- \( T_{out} \) is the temperature of the air leaving the layer, in K;
- \( T_{in} \) is the temperature of the air entering the layer, in K;
\( T_{in} \) is the temperature of the air entering the air layer, in K.

with

\[ q_a = r \cdot v \cdot A_a \]  

(B.18)

where \( A_a \) is the area of the cross section of the air flow.

\[ T_{out} = T_{av} - \left[ T_{av} - T_{eq} \right] e^{-1/\varepsilon_t} \]  

(B.19)

— due to the convective heat exchanges with the surfaces \( n-1 \) and \( n \) delimiting the air layer:

\[ \phi_{c,n-1} = h_c \cdot A_c (T_{n-1} - T_{eq}) \]  

(B.20)

\[ \phi_{c,n} = h_c \cdot A_c (T_n - T_{eq}) \]  

(B.21)

where \( A_c \) is the area of the adjacent surfaces.

**B.3 Convective heat transfer for an external horizontal air layer**

**B.3.1 General**

A similar calculation for an external horizontal air layer is made (Figure B.3). In this case, the driving pressure difference \( \Delta p_w \) derives from the wind velocity as follows:

\[ \Delta p_w = \Delta C_{pr} \cdot \frac{1}{2} \cdot \rho \cdot v^2 \]  

(B.22)

where

\( \Delta C_{pr} \) is the difference in the pressure coefficients between the inlet and the outlet of the air layer;

\( v \) is the wind velocity.

\( \Delta C_{pr} \) assumes values changing from 0 (no openings perpendicular to the wind direction) to 1.

The total pressure losses \( \Delta p_T \) are calculated according to Equation (B.8). The velocity \( v \) in the ventilated air layer is obtained by solving the following:

\[ \Delta p_w = \Delta p_T \]  

(B.23)

---

**Figure B.3 - Example of horizontal air layer**
B.3.2 Evaluation of the convective heat transfer for horizontal air layer

The convection heat transfers are calculated as in B.2.1.2:

— due to the air motion $\Phi_v$, according to Equation (B.17);

— due to the convective heat exchanges with the surfaces $n - 1$ and $n$ delimiting the air layer, $\Phi_c$, according to Equation (B.20) and Equation (B.21).
Annex C
(informative)

Shading due to overhangs and side fins

C.1 Introduction

This annex includes a procedure for determining the shaded area of a building element when obstructions due to an overhang and side fin are present.

The equations recognize wall solar azimuth angle $\gamma$ and solar altitude $\beta$ as known angles (Figure C.1). Other dimensions for a window of length $L$ and height $H$ are shown in Figure C.2 for an overhang and Figure C.3 for a side fin. Various shapes of shadows on a window are shown in Figure C.4. Shadows for an overhang, for an overhang with a vertical end projection, and for side fins, are separated to simplify the equations and their calculation procedure. After all types of shadows have been established, the procedure will then add up all the shadow areas for use in the final solar contribution.

![Figure C.1 - Solar azimuth angle $\gamma$ and solar altitude $\beta$](image-url)
In this annex the following calculations are introduced:

a) calculation path for overhang;

b) calculation path for vertical projection and the end of the overhang;

c) calculation path for side fin;

d) calculation path for sunlit area due to short side fin.

### C.2 Calculation path for overhang

The width of the overhang is assumed to be equal to or greater than that of the window. The overhang can be located at the head of the window, or at distance $a$ above the head of the window. Figure C.4 shows a typical shadow cast by an overhang. Aside from the fixed physical dimensions of the window arrangement $L$, $H$, $a$ and $b$, all equations are expressed in terms of the shadow depth $T$ and the shadow offset $M$ cast by overhang, where:

$$T = P \frac{\tan \beta}{\cos \gamma}$$

$$M = P \tan \gamma$$

(C.1)
The areas of the shadow shapes cast by an overhang, reported in Figure C.4 from SS01 to SS09, are as follows:

\[ A_{01} = 0 \]
\[ A_{02} = H L \]
\[ A_{03} = L (T - a) \]
\[ A_{04} = (T - a)[L + b - \frac{M(1 + \frac{a}{T})}{2}] \]
\[ A_{05} = H \left[ L - [(a + H, \frac{M}{T})/2] + b \right] \]
\[ A_{06} = \left\{ \left[ (L + b) \frac{T}{M} \right] - a \right\}^2 \left( \frac{M}{2T} \right) \]
\[ A_{07} = \left[ (T - a) L - \left[ (M - b)^2 \frac{T}{2M} \right] \right] \]
\[ A_{08} = H L - \left\{ (H + a) \frac{M}{T} - b \right\}^2 \frac{T}{2M} \]
\[ A_{09} = L \left[ (b + L) \frac{T}{M} - a \right] \]

(C.2)

### C.3 Calculation path for vertical projection at the end of the overhang

The width of the vertical projection is assumed to be equal to that of the overhangs. The area equations for the shadow shapes cast by a vertical projection at the end of an overhang, showed in Figure C.5 from SSV1 to SSV9, are as follows:

\[ A_{v1} = 0 \]
\[ A_{v2} = H L \]
\[ A_{v3} = L (T + d - a) \]
\[ A_{v4} = H (L + b - M) \]
\[ A_{v5} = (T + d - a)(L + b - M) \]
\[ A_{v6} = L d \]
\[ A_{v7} = L (H + a - T) \]
\[ A_{v8} = (L + b - M) d \]
\[ A_{v9} = (L + b - M)(H + a - T) \]

(C.3)

![Figure C.5 - Shadow shapes of vertical projections at the end of overhangs](image)
C.4 Calculation path for side fin

In order to include shadows cast by a sun hood (external shading device consisting of an overhang and side fins covering only the upper part of the window) or by the side of a balcony, fins are assumed to have any length greater than, less than or equal to the height of a window. They can be located at the window jamb, or a distance \( b' \) away from window jamb (Figure C.3). Dimension \( a' \) is considered positive when the fin extends above the window and negative when it stops below the head of the window. Dimension \( c' \) is considered to be zero in this part of calculation. Any sunlit area, resulting from a short fin that stops above the window sill level, will be deducted in the fourth part of the calculation. The calculation path for the side fin is very similar to that of the overhang. The area equations for the shadow shapes cast by the side fins, shown in Figure C.6 from SSF1 to SSF9, are the following:

\[
\begin{align*}
A_{F1} &= 0 \\
A_{F2} &= H \ L \\
A_{F3} &= H \ (M'-b') \\
A_{F4} &= (M'-b') \left[ (H+a')-\left\{ \frac{T' \ (1+\frac{b'}{M'})}{2} \right\} \right] \\
A_{F5} &= L \left\{ H-\left[ \left( b'+\frac{L}{2} \right) \frac{T'}{M'} \right] + a' \right\} \\
A_{F6} &= \left( (H+a') \ M' / T' \right) - b' \left( \frac{T'}{2M'} \right) \\
A_{F7} &= [(M'-b') \ H] - [(T'-a') \ M' / 2T'] \\
A_{F8} &= H \ L \left( [(L+b') \ M' / T'] - a' \right) \left( \frac{M'}{2T'} \right) \\
A_{F9} &= H \left( (a'+\frac{H}{2}) \frac{M'}{T'} - b' \right)
\end{align*}
\]

\[(C.4)\]

Figure C.6 - Shadow shapes of side fins

It should be noted that these equations have the same form as the equations for the overhang with variables \( T, M, H, L, a \) and \( b \) replaced by \( M', T', L, H, a' \) and \( b' \) respectively.
C.5 Calculation of the sunlit area due to short side fin

The shadow area equations for the various situations shown in Figure C.7 from SF1 to SF4 are the following:

\[
\begin{align*}
A_{SF1} &= 0 \\
A_{SF2} &= -(M'-b') \left( c' - [T' \left( \frac{1 + b'/M'}{2} \right) \right] \\\nA_{SF3} &= -L \left( c' - (b'/L/2) \frac{T'}{M'} \right) \\\nA_{SF4} &= -[c' - (b'/M')]^2 \frac{M'}{M'} \quad (C.5)
\end{align*}
\]

![Figure C.7- Shapes of sunlit area due to short side fins](image)

The minus signs indicate that these areas, if they occur, should be deducted from the previously accumulated shadow areas. The accumulation process is now necessary when different solutions are present. The algorithm, guided by a series of control statements, enters the shadow evaluation process and follows a single path through the flow chart. Along each of the path segments, the algorithm calculates and accumulates a particular set of shadow areas cast by overhang, vertical projection and side fin T' and shadow for use in the solar contribution for calculation. The shading devices considered in this algorithm are those of the most commonly used shapes. Other shapes can be introduced by expanding it.

C.6 External obstruction

When external obstructions are present, the following procedure can be used to determine the shaded area. This procedure is approximate and it is applicable when the wall or window is relatively small in comparison to the shading object. The wall or window is considered either completely shaded or completely in the sun. A partially shaded wall or window can be considered as either completely shaded or completely in the sun depending on the location of the wall reference point. Figure C.8 shows a typical wall-shading object relationship. It should be noted that the reference point may be located at any point on the wall or window. Locating the reference point at the top of the wall or window, as shown in the elevation in Figure C.8 is slightly conservative as compared to the reference point located at the centre of the wall or window. For the application of the procedure the following data are required:

- azimuth shaded angles \( \alpha_1, \alpha_2 \) (right + , left -);
- altitude shadow limit angles \( \delta_1, \delta_2 \)
- wall azimuth angle \( \omega \)
- solar azimuth angle \( \gamma \)
- solar altitude angle \( \beta \)
- limiting points of obstruction \( M, N \)
This procedure determines whether the wall is sunlit or shaded.

For the given position of the sun:

a) determine the wall-solar azimuth angle \( \chi = \gamma - \omega \)

b) if \( \chi < \alpha_1 \) or \( \chi > \alpha_2 \) the window is in sun;
c) $\alpha_2 > \chi > \alpha_1 \quad A = \chi - \alpha_1 \cdot B = \delta_1 + A (\delta_2 - \delta_1)$

d) if $\beta > B$ the wall is in sun; otherwise it is in shade.

### C.7 Sunlit factor

The area equations in C.2 to C.6 determine the amount of the shaded area $A_{sh}$ of the component.

The sunlit area is given by:

$$A_s = A - A_{sh} \quad \text{(C.6)}$$

The sunlit factor $f_s$ is determined as:

$$f_s = 1 - A_s/A \quad \text{(C.7)}$$

where

- $A_s$ is the shaded area;
- $A$ is the total area.
Annex D
(informative)

Design climatic data in the warm season

Design warm weather conditions (cloudless sky) occur on relatively few days in summer. If solar radiation produces a large proportion of heat flow, it is essential to calculate the internal temperature for several months separately. As a consequence, design climatic data should be generally defined for all months. In the absence of a standard\(^1\) on climatic data, the following characteristics of the design climatic data for design temperature calculations can be used.

1) From a long-term data set, identify for each month and for each year the hottest 4-day spell. These are defined as a non-overlapping period of 4 days with the highest average of daily mean temperature.

2) For the chosen month identify discrete 4-day spells with an average period of one per year. This would mean looking at daily temperature data for each day of the chosen month and selecting, for example, the hottest 20 spells from a 20-year data set.

3) Exclude 50 % of these spells on the basis of low average temperature (those 4-day average of daily mean temperatures which lie below the median, where the 4-day averages are rounded to the nearest 0,5 °C).

4) Exclude 50 % of remaining spells on the basis of high diurnal range (those whose 4-day average of daily temperature range which lie above the median; where the 4-day averages are rounded to the nearest 0,5 °C).

This will produce a final selection of 4-day spells of critical conditions with a return period of 4 years.

5) Calculate the hourly averages of temperature and radiation for each hour in each day in the selected spells and take these as design values.

6) Calculate the averages of daily mean wind speed for each day in the selected spells and take these as design values for the corresponding day in the 4-day sequence.

\(^1\) Under preparation within CEN/ TC 89
Annex E
(informative)

Calculation of the internal long-wave radiation exchanges in buildings

E.1 Introduction

This annex gives a simplified procedure for evaluating the internal long-wave radiation exchanges in buildings.

E.2 Limits of application

The procedure can be applied for situations where

— the emissivities of the various surfaces are similar;
— the geometry of the room is simple (rectangular).

For special situations it should be referred to the solution techniques reported in scientific literature (see Bibliography).

E.3 Calculation procedure

The total net long-wave radiation at the \( n \)th internal surface is calculated by assuming that each surface \( n \) radiates to a fictitious surface \( f \), which has the following characteristics:

\[
\begin{align*}
\text{area } & \quad A = \sum_{n=1}^{N} (A)_n \quad (N = \text{number of the internal surfaces}) \quad (E.1) \\
\text{emissivity } & \quad \varepsilon_f = \frac{\sum_{n=1}^{N} (\varepsilon_n A_n)}{A_f} \quad (E.2) \\
\text{temperature } & \quad T_f = \frac{\sum_{n=1}^{N} (A_n \varepsilon_n T_n)}{\varepsilon_f A_f} \quad (E.3)
\end{align*}
\]

The density of radiant heat flow rate \( q_{\text{in},k} \) from a surface \( k \) to the others is:

\[
q_{\text{in},k} = (q_{\text{in},k} - q_{\text{bal}}) \quad (E.4)
\]

where

\[
q_{\text{in},k} = \sigma F_k (T_f^4 - T_k^4) \quad (E.5)
\]

\[
F_k = \left(1 + \frac{1 - \varepsilon_k}{\varepsilon_k} + \frac{A_k (1 - \varepsilon_k)}{A_f \varepsilon_f}\right) \quad (E.6)
\]

\[
q_{\text{bal}} = \sum_{k=1}^{N} (q_{\text{in},k} A_k) / A_f \quad (E.7)
\]
Annex F
(informative)

External radiative long-wave heat transfer coefficients

F.1 Introduction

This annex gives the terms influencing the long-wave radiation exchanges at the external surfaces and provides a procedure for the evaluation of the external long-wave heat transfer coefficient.

F.2 Terms and calculation procedure

Long-wave radiation is emitted by all solids, fluids and most gaseous molecules. External building elements exchange radiation with the sky, the ground, surrounding buildings and plants. For the long-wave radiation balance the view factor $F$ between each environmental radiator and the surface is very important. Assuming that all surrounding radiators are black bodies and the surface considered has an emissivity $\varepsilon$, the net long-wave radiant flux density $q_{lr,e}$ for an external surface is calculated as:

$$q_{lr,e} = \varepsilon \sigma (F_{sk} T_{sk}^4 + F_{b} T_{b}^4 + F_{g} T_{g}^4 - T_{es}^4)$$  \hspace{1cm} (F.1)

where

- $F_{sk}$ is the view factor with the sky;
- $F_{b}$ is the view factor with other buildings;
- $F_{g}$ is the view factor with the ground;
- $T_{sk}$ is the absolute temperature of the sky;
- $T_{b}$ is the absolute temperature of other buildings;
- $T_{g}$ is the absolute temperature of the ground;
- $T_{es}$ is the external surface temperature of the wall;
- $\varepsilon$ is the emissivity of the surface;
- $\sigma$ is the Stefan-Boltzmann constant.

View factors depend on the orientation of the surface and on the type of the environments. Table F.1 gives typical view factors for different situations.

<table>
<thead>
<tr>
<th>Type of &quot;environment&quot;</th>
<th>Vertical surface</th>

</table>

<table>
<thead>
<tr>
<th>Horizontal surface (roof)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$F_{sk}$</td>
</tr>
<tr>
<td>All environments</td>
</tr>
</tbody>
</table>
The temperatures included in Equation (F.1) are approximated as follows:

\[ T_{sk} = \left[ 9.36 \times 10^{-6} \left( T_{a,e} \right)^6 \right]^{0.25} \]  
\[ (F.2) \]

\[ T_b = T_{a,e} \]

\[ T_g = T_{a,e} \]

where \( T_{a,e} \) is the external air temperature, in kelvins.

Equation (F.1) can be written as:

\[ q_{ir,e} = h_{r,e} \left( T_{a,e} - T_{es} \right) + q_{e,r} \]  
\[ (F.3) \]

with

\[ h_{r,e} = 4 \varepsilon \sigma T_m^3 \]  
\[ (F.4) \]

\[ q_{e,r} = F_{sk} \varepsilon \sigma \left( T_{sk}^4 - T_{a,e}^4 \right) \]  
\[ (F.5) \]

\[ T_m = \left( T_{a,e} + T_{s,e} \right) / 2 \]  
\[ (F.6) \]
Annex G
(informative)

Solar factors

G.1 Introduction

This annex gives the procedures for determining the solar factors introduced in 4.5.3.2 of the document.

G.2 Solar to air factor

The solar to air factor, \( f_{sa} \), is the fraction of the solar heat entering through the glazing and immediately transferred to the internal air. This fraction depends on the quantity of internal items with very low thermal capacity, such as carpets and furniture. Typical values of the solar to air factor are given in Table G.1 according to the amount of furniture.

<table>
<thead>
<tr>
<th>Amount of furniture</th>
<th>Solar to air factor ( f_{sa} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>No furniture</td>
<td>0</td>
</tr>
<tr>
<td>Small amount of furniture</td>
<td>0.10</td>
</tr>
<tr>
<td>Large amount of furniture</td>
<td>0.20</td>
</tr>
</tbody>
</table>

G.3 Distribution factors

The distribution factors, \( f_{df} \), are the fraction of the direct solar radiation absorbed per area of the different internal surfaces of the walls, ceiling, floor, etc. They depend on the solar angles, the geometrical dimensions of glazing and the room, the short-wave reflectance of components, and the furniture and furnishings. It is assumed to be time independent. Typical values of the distribution factors are given in Table G.2 as a function of the area-weighted average reflectance, \( \rho_m \), and the area of the envelope elements.

<table>
<thead>
<tr>
<th>Room reflectance</th>
<th>Floor</th>
<th>Vertical walls</th>
<th>Ceiling</th>
<th>Glazing</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \rho \geq 0.7 )</td>
<td>( 1/A_T )</td>
<td>( 1/A_T )</td>
<td>( 1/A_T )</td>
<td>( 1/A_T )</td>
</tr>
<tr>
<td>( 0.3 \leq \rho &lt; 0.7 )</td>
<td>( 0.5/A_f )</td>
<td>( 0.4/A_{wa} )</td>
<td>( 0.1/A_c )</td>
<td>( 0.0 )</td>
</tr>
<tr>
<td>( \rho &lt; 0.3 )</td>
<td>( 0.6/A_f )</td>
<td>( 0.35/A_{wa} )</td>
<td>( 0.05/A_c )</td>
<td>( 0.0 )</td>
</tr>
</tbody>
</table>

where

- \( A_T \) is the floor area, in m\(^2\);
- \( A_{wa} \) is the area of all (external and internal) vertical opaque walls, in m\(^2\).
EN ISO 13791:2004 (E)

\( A_c \) is the ceiling/roof area, in m\(^2\);

\( A_T \) is the total envelope area excluding glazing, in m\(^2\).

The area weighted average reflectance is given by:

\[
\rho_m = \frac{\sum_{j=1}^{N} A_j \rho_j}{\sum_{j=1}^{N} A_j}
\]

(G.1)

**G.4 Solar loss factor**

The solar loss factor, \( f_{lf} \), is the fraction of the solar radiation entering through the glazing and reflected back to the external environment. It depends on the geometrical characteristics and solar properties of the glazing system, the exposure of the window, the solar angles and the room colour and geometry. It is assumed to be time independent. A detailed and exact calculation method of the short wave radiation back to the window, is much too complicated for the purposes of this document. It is nevertheless possible to apply here a simplified approach considering the following assumptions:

- the view factors for the various internal surfaces are not considered;
- the solar reflection factor for all surfaces is the same;
- the solar transmittance of the glazing system refers to the direct solar radiation component.

The solar loss factor is given by:

\[
f_{lf} = \frac{\tau A_w}{A_t (1 - \rho_m)}
\]

(G.2)

where

\( \tau \) is the solar transmittance of the glazing system;

\( A_w \) is the window area;

\( A_t \) is the room overall surface area;

\( \rho_m \) average solar reflection coefficient of room surfaces (defined in Equation (G.1)).

Examples of solar loss factors for different room geometries and solar transmittance of glazing components are given in Table G.3 for a room having an average solar reflection of 0,5 and height 2,7 m.

Annex J
(informative)

Air ventilation

J.1 Introduction

This annex gives a procedure for the evaluation of the air flow rate due to natural ventilation through the openings in building. In the absence of a standard giving a detailed model based on the air mass balance, this annex can be used.

J.2 Calculation procedure

J.2.1 General

The amount of air flowing into the building depends upon the pressure difference between the internal and the external environments and also on the resistance that any openings give to the flow of air. The pressure difference is produced by the action of the wind flow around the building and by the difference in the density of the internal and external air. The aerodynamics of the air flowing are complex but, by deeming openings to be classifiable within two general types, it is possible to specify simple formulae to relate the flow rate to the pressure difference. These categories are:

a) cracks, or small openings with a typical dimension less than approximately 10 mm;

b) openings with a typical dimension larger than approximately 10 mm.

J.2.2 Cracks and small openings

For cracks the ventilation rate is given as:

\[ m = \rho \ k \ l \ (\Delta p)^n \]  \hspace{1cm} (J.1)

where

\( \rho \) is the density of the air;

\( k \) is the crack coefficient;

\( l \) is the length of the crack, in metres;

\( \Delta p \) is the applied pressure difference, in Pa.

Table J.1 gives a range of values of \( k \) for the cracks formed around the openings lights of closed windows, which can be used when national values are not available. A suitable value for \( n \) is 0.67. The pressure difference between internal and external environments is obtained by adding the thermal buoyancy \( \Delta p_T \) and the wind contribution \( \Delta p_w \).

\[ \Delta p = \Delta p_T + \Delta p_w \]  \hspace{1cm} (J.2)

The thermal buoyancy \( \Delta p_T \) contribution is given by:

\[ \Delta p_T = (\Delta T \ \rho \ g \ H_i / T_m)^{0.5} \]  \hspace{1cm} (J.3)

where

\( \Delta T \) is the temperature difference between internal and external environments;
\[ T_m \] is the reference temperature (300 K);
\[ g \] is the acceleration due to gravity (\( = 9.81 \text{ m/s}^2 \));
\[ \rho \] is the air density;
\[ H_1 \] is the height between high and low level.

The wind contribution \( \Delta p_w \) is given by:
\[
\Delta p_w = \rho \frac{v_r^2}{2}
\]
(J.4)

where
\[ \rho \] is the air density;
\[ v_r \] is the wind reference velocity.

**Table J.1 - Values of \( k \) for windows (in litres per second and per metre of crack length for an applied pressure difference of 1 Pa)**

<table>
<thead>

</tr>
<tr>
<td>Pivoted (weather stripped)</td>
<td>0.08</td>
</tr>
</tbody>
</table>

**J.2.3 Large openings**

**J.2.3.1 General**

The air flow rate can be evaluated by the approximate formula:
\[
m = \rho \ c_d \ A \left(2 \frac{\Delta p}{\rho}\right)^{0.5}
\]
(J.5)

where
\[ c_d \] is the coefficient of discharge;
\[ A \] is the area of opening;
\[ \Delta p \] is the pressure difference;
\[ \rho \] is the air density.

Values of the coefficient \( c_d \) and area \( A \) depend on the position and flow characteristics of all openings. It is usual to assign a value to the discharge coefficient corresponding to that for a sharp-edged orifice, taken here as 0.61. The value of \( A \) for other types of opening then becomes the equivalent area associated with that particular opening. Pressure generated by forces of wind and temperature difference produces a movement of air through these openings governed by the fact that the total flow of air into the circulation space equals the outgoing flow rate. Because of the impossibility to obtain a detailed solution for existing buildings, the solution is given for simple cases.
Figure J.2 shows a simple two dimensional representation of a building with no internal divisions and therefore consisting of a single cell with openings as shown, i.e. two \((A_1\) and \(A_3\)) at high level, and two \((A_2\) and \(A_4\)) at low level. According to the wind and temperature situation the air flow by natural ventilation is determined as follows. Figure J.3 shows a similar representation for a building without any internal partition and with openings on one side and one level only.

**J.2.3.2 Simple buildings: openings on two facades**

**J.2.3.2.1 Wind only**

\[ m_w = c_d A_w v_r (\Delta c_p)^{0.5} \]  

\[(J.6)\]

and

\[ v_r = K z^a v_f \]  

\[(J.7)\]

where

- \(K\) is a coefficient as given in Table J.3;
- \(a\) is an exponent as given in Table J.3;
- \(z\) is the height of the building, in metres;
- \(v_f\) is the free wind velocity, in m/s.

\[ \frac{1}{A_w^2} = \frac{1}{(A_1 + A_2)^2} + \frac{1}{(A_3 + A_4)^2} \]  

\[(J.8)\]

where \(\Delta c_p\) is the applied differential mean pressure coefficient calculated as difference between the mean surface pressure coefficients, derived from Table J.2 for the opposite walls perpendicular to the wind direction.

J.2.3.2.2 Temperature difference only

\[ m_T = c_d \rho A_T (2 \Delta \theta g H_1 / T_m)^{0.5} \]  

(J.9)

\[ \frac{1}{A_T^2} = \frac{1}{(A_1 + A_2)^2} + \frac{1}{(A_3 + A_4)^2} \]  

(J.10)

where

- \( c_d \) is the coefficient of discharge;
- \( m_T \) is the mass flow rate due to temperature difference;
- \( \Delta \theta \) is the temperature difference between internal and external environments;
- \( T_m \) is the reference temperature (300 K);
- \( g \) is the acceleration due to gravity (= 9,81 m/s²);
- \( H_1 \) is the height between high and low level.

J.2.3.2.3 Wind and temperature difference together

\[ m = m_T \quad \text{for} \quad \nu_f / (\Delta T)^{0.5} < (0.26 (A_T / A_w)^{0.5} (H_1 / \Delta c_p)^{0.5}) \]

\[ m = m_w \quad \text{for} \quad \nu_f / (\Delta T)^{0.5} > (0.26 (A_T / A_w)^{0.5} (H_1 / \Delta c_p)^{0.5}) \]  

(J.11)

J.2.3.3 Openings in one wall only

J.2.3.3.1 Wind

\[ m_w = 0.025 \, A \, v_f \]  

(J.12)

where \( v_f \) is defined by Equation (J.7).

J.2.3.3.2 Temperature differences with openings at two levels

\[ m_T = c_d \rho A \left( \frac{2 \Delta \theta g H_1}{T_m} \right)^{0.5} \]  

(J.13)

where

- \( A_T \) is determined from Equation (J.10);
- \( c_d \) is the coefficient of discharge.

J.2.3.3.3 Temperature difference with openings at one level only

\[ m_T = c_d \rho A \left( \frac{\Delta \theta g H}{T_m} \right)^{0.5} \]  

(J.14)

where \( H \) is the opening height.
J.3 Example of calculation of natural ventilation rates for simple building

J.3.1 General
Consider a building consisting of a single undivided space 25 m long, 10 m wide and 8 m high. Given that the building is situated in an open suburban area, calculate:

a) the natural ventilation rate due to wind;

b) the ventilation rate due to the effect of a temperature difference of 6 K in the absence of the wind.

There are no ventilation openings on the shorter walls. On each of the longer walls there are openings of 2,5 m$^2$ at low level, and 5,0 m$^2$ at high level, separated by a vertical distance of 6,0 m, and evenly distributed along the length of the wall.

J.3.2 Wind

Determination of the pressure coefficient difference

Building height ratio = 0,8
Building plan ratio = 2,5

Thus, from Table J.2, the difference in mean surface pressure coefficients at the two long sides A and C of the building for a perpendicular wind is:

\[ \Delta c_p = 0,7 - (- 0,3) = 1,0 \]

Determination of \( v_r \)

From climatic data table \( v_r = 3,75 \) m/s

terrain: country with scattered wind breaks :

From Table J.3: \( K = 0,52 \); \( a = 0,20 \)

Thus, from Equation (J.7), using the building height of 8 m,

\[ v_r = 3,75 \times 0,52 (8)^{0,2} = 2,96 \text{ m/s} \]

Determination of \( A_w \)

From Equation (J.8):

\[ \frac{1}{(A_w)^2} = \frac{1}{(5,0 + 2,5)^2} + \frac{1}{(5,0 + 2,5)^2} \]

\[ A_w = 5,3 \text{ m}^2 \]

Determination of ventilation rate

Using Equation (J.6):

\[ m_w = (0,61 \times 5,3 \times 2,96 \times 1)^{0,5} = 3,09 \text{ m}^3 /\text{s} \]

The volume of the building is \( V = 25 \times 10 \times 8 = 2000 \text{ m}^3 \)

The air change rate is \( 3600 \times 3,09 / 2000 = 5,57 \text{ air changes/hour} \)

J.3.3 Temperature difference

From the information given:
Temperature difference $\Delta \theta = 6$ K

Height between openings $H_1 = 6.0$ m

Thus from Equation (J.10):

$$\frac{1}{(A_T)^2} = \left( \frac{1}{(2.5 + 2.5)^2} \right) + \left( \frac{1}{(5.0 + 5.0)^2} \right)$$

$$A_T = 4.47 \text{ m}^2$$

Taking $T_m = 300$ K and $\rho = 1.2 \text{ kg/m}^3$

$$m_T = 0.61 \times 1.2 \times \frac{4.47}{3} \times \left( \frac{6 \times 9.8 \times 6}{300} \right)^{0.5} = 1.183 \text{ m}^3/\text{s}$$

The air change rate is:

$$3600 \times 1.183 / 2000 = 2.13 \text{ air changes/hour}$$

Annex K
(informative)

Detailed results of the validation tests considered in the “whole validation model” procedure

This annex gives the hourly values of the operative temperature for the various tests considered in the “whole calculation method” included in 7.3.
